# CHAPTER 1 OUTLINE

The E0C63567 is a microcomputer which has a high-performance 4-bit CPU E0C63000 as the core CPU, ROM (16,384 words × 13 bits), RAM (5,120 words × 4 bits), serial interface, watchdog timer, programmable timer, time base counters (2 systems), SVD circuit, a dot-matrix LCD driver that can drive a maximum 60 segments × 17 commons, DTMF/DP generator and sound generator built-in. The E0C63567 features high speed operation and low current consumption in an operating voltage range (2.2 V to 5.5 V), this makes it suitable for applications working with batteries. It is also suitable for caller ID and portable data bank systems because it has a large capacity of RAM built-in.

## 1.1 Features

OSC1 oscillation circuit .....	32.768 kHz (Typ.) crystal or 60 kHz (Typ.) CR oscillation circuit (*1)
OSC3 oscillation circuit .....	3.58 MHz (Typ.) ceramic or 1.8 MHz (Typ.) CR oscillation circuit (*1)
Instruction set .....	Basic instruction: 46 types (411 instructions with all) Addressing mode: 8 types During operation at 32.768 kHz: 61 μsec 122 μsec 183 μsec During operation at 3.58 MHz: 0.56 μsec 1.12 μsec 1.68 μsec
ROM capacity .....	Code ROM: 16,384 words × 13 bits Data ROM: 2,048 words × 4 bits (= 8K bits)
RAM capacity .....	Data memory: 5,120 words × 4 bits Display memory: 1,020 bits (240 words × 4 bits + 60 × 1 bit)
Input port .....	8 bits (Pull-up resistors may be supplemented *1)
Output port .....	12 bits (It is possible to switch the 8 bits to special output *2)
I/O port .....	16 bits (It is possible to switch the 2 bits to special output and the 4 bits to serial I/F input/output *2)
Instruction execution time .....	
Serial interface .....	Built-in (8-bit clock synchronous or asynchronous system is selectable)
LCD driver .....	60 segments × 8, 16 or 17 commons (*2)
Time base counter .....	2 systems (Clock timer, stopwatch timer)
Programmable timer .....	Built-in, 2 inputs × 8 bits, with event counter function
Watchdog timer .....	Built-in
DTMF generator .....	Built-in
DP generator .....	Built-in
Sound generator .....	With envelope and 1-shot output functions
Supply voltage detection (SVD) circuit...	12 values, programmable (2.20 V to 3.30 V) (It is possible to switch 1 value to the external voltage detection *1)
External interrupt .....	Input port interrupt: 2 systems
Internal interrupt .....	Clock timer interrupt: 4 systems Stopwatch timer interrupt: 2 systems Programmable timer interrupt: 2 systems Serial interface interrupt: 3 systems Dialer interrupt: 1 system
Power supply voltage .....	2.2 V to 5.5 V
Operating temperature range .....	-20°C to 70°C
Current consumption (Typ.) .....	Low-speed operation (OSC1: crystal oscillation): During HALT (32 kHz) 3.0 V (LCD power OFF) 1.5 μA 3.0 V (LCD power ON) 4 μA During operation (32 kHz) 3.0 V (LCD power ON) 10 μA High-speed operation (OSC3: ceramic oscillation): During operation (3.58 MHz) 3.0 V (LCD power ON) 1,000 μA
Package .....	QFP8-144pin (plastic) or chip

\*1: Can be selected with mask option \*2: Can be selected with software

## 1.2 Block Diagram

## 1.4 Pin Description

Table 1.4.1 Pin description

Pin name	Pin No.	I/O	Function
VDD	33	–	Power (+) supply pin
VSS	27	–	Power (–) supply pin
VD1	30	–	Oscillation system regulated voltage output pin
VC1–VC5	81–84	–	LCD system power supply pin (1/4 bias generated internally)
CA–CC	87–85	–	LCD system boosting/reducing capacitor connecting pin
OSC1	28	I	Crystal oscillation input pin
OSC2	29	O	Crystal oscillation output pin
OSC3	31	I	Ceramic oscillation input pin
OSC4	32	O	Ceramic oscillation output pin
K00–K03	79–76	I	Input port
K10–K13	75, 74, 69, 68	I	Input port
P00–P03	67–64	I/O	I/O port
P10–P13	63–60	I/O	I/O port (switching to serial I/F input/output is possible by software)
P20	59	I/O	I/O port
P21	58	I/O	I/O port
P22	57	I/O	I/O port (switching to CL signal output is possible by software)
P23	56	I/O	I/O port (switching to FR signal output is possible by software)
P30–P33	55–52	I/O	I/O port
R00	51	O	Output port (switching to XBZ signal output is possible by software)
R01	50	O	Output port (switching to BZ signal output is possible by software)
R02	49	O	Output port (switching to TOUT signal output is possible by software)
R03	48	O	Output port (switching to FOUT signal output is possible by software)
R10	47	O	Output port (switching to XTMUTE signal output is possible by software)
R11	46	O	Output port (switching to XRMUTE signal output is possible by software)
R12	45	O	Output port (switching to HDO signal output is possible by software)
R13	44	O	Output port (switching to HFO signal output is possible by software)
R20–R23	43–40	O	Output port
COM0–COM16	26–19, 88–96	O	LCD common output pin (1/8, 1/16, 1/17 duty can be selected by software)
SEG0–SEG59	18–2, 142–112, 108–97	O	LCD segment output pin
SVD	80	I	SVD external voltage input pin
DP	39	O	Dial pulse output pin
TONE	36	O	DTMF output pin
RESET	34	I	Initial reset input pin
TEST	35	I	Testing input pin

## 1.5 Mask Option

Mask options shown below are provided for the E0C63567. Several hardware specifications are prepared in each mask option, and one of them can be selected according to the application. The function option generator winfog, that has been prepared as the development software tool of E0C63567, is used for this selection. Mask pattern of the IC is finally generated based on the data created by the winfog. Refer to the "E0C63 Family Development Tool Manual" for the winfog.

### <Functions selectable with E0C63567 mask options>

#### (1) *OSC1 oscillation circuit*

Either crystal oscillation circuit or CR oscillation circuit can be selected as the OSC1 oscillation circuit. Refer to Section 4.3.2, "OSC1 oscillation circuit", for details.

#### (2) *OSC3 oscillation circuit*

Either CR oscillation circuit or ceramic oscillation circuit can be selected as the OSC3 oscillation circuit. Refer to Section 4.3.3, "OSC3 oscillation circuit", for details.

#### (3) *External reset by simultaneous LOW input to the input port (K00–K03)*

This function resets the IC when several keys are pressed simultaneously. The mask option is used to select whether this function is used or not. Further when the function is used, a combination of the input ports (K00–K03), which are connected to the keys to be pressed simultaneously, can be selected. Refer to Section 2.2.2, "Simultaneous low input to terminals K00–K03", for details.

#### (4) *Time authorize circuit for the simultaneous LOW input reset function*

When using the external reset function (shown in 3 above), using the time authorize circuit or not can be selected by the mask option. The reset function works only when the input time of simultaneous LOW is more than the rule time if the time authorize circuit is being used. Refer to Section 2.2.2, "Simultaneous low input to terminals K00–K03", for details.

#### (5) *Input port pull-up resistor*

The mask option is used to select whether the pull-up resistor is supplemented to the input ports or not. It is possible to select for each bit of the input ports. Refer to Section 4.4.3, "Mask option", for details.

#### (6) *Output specification of the output port*

Either complementary output or N-channel open drain output can be selected as the output specification for the output ports. The selection is done in 1-bit units. Refer to Section 4.5.2, "Mask option", for details.

#### (7) *Output specification / pull-up resistor of the I/O ports*

Either complementary output or N-channel open drain output can be selected as the output specification when the I/O ports are in the output mode. The selection is done in 1-bit units.

Further, whether or not the pull-up resistors working in the input mode are supplemented can be selected. The selection is done in 1-bit units or 4-bit units depending on the I/O port.

1-bit unit: P20, P21, P22, P23

4-bit unit: P00–P03, P10–P13, P30–P33

Refer to Section 4.6.2, "Mask option", for details.

**(8) Output specification of other special output terminals**

The following special output terminals are shared with the output (R) terminals or the I/O (P) terminals. Consequently, the output specification (complementary output or N-channel open drain output) of the shared terminal applies to the special output.

Special output signal	Shared port
XBZ, BZ, TOUT, FOUT	Output ports R00–R03
XRMUTE, XTMUTE, HDO, HFO	Output ports R10–R13
Serial interface input/output	I/O ports P10–P13
CL, FR	I/O ports P22, P23

**(9) Output specification of the  $\overline{DP}$  terminal**

Either complementary output or N-channel open drain output can be selected as the output specification for the  $\overline{DP}$  (dial pulse output) terminal.

Refer to Section 4.14.2, "Mask option", for details.

**(10) External voltage detection of SVD circuit**

External voltage (SVD terminal–Vss terminal) detection can be selected in addition to supply voltage (VDD terminal–Vss terminal) detection. The SVD terminal is used to input the external voltage to be detected.

Refer to Section 4.13.2, "Mask option", for details.

**(11) Tone duration time selection (DTS) for DTMF circuit**

It can through DTS control resistor to select 94 msec or 47 msec for tone duration time, when this mask option is selected as "use". Otherwise, the tone duration time will be fixed at 94 msec.

Refer to section 4.14.2 "Mask option" for details.

**<Mask Option List>**

The following is the option list for the E0C63567.

Multiple selections are available in each option item as indicated in the option list. Using "Chapter 4 Peripheral Circuits and Operation" as reference, select the specifications that meet the target system and check the appropriate box. Be sure to record the specifications for unused functions too, according to the instructions provided. Refer to the "E0C63 Family Development Tool Manual" for the winfog.

**1. OSC1 SYSTEM CLOCK**

- 1. Crystal
- 2. CR

**2. OSC3 SYSTEM CLOCK**

- 1. Ceramic
- 2. CR

**3. MULTIPLE KEY ENTRY RESET COMBINATION**

- 1. Not Use
- 2. Use (K00, K01, K02, K03)
- 3. Use (K00, K01, K02)
- 4. Use (K00, K01)

**4. MULTIPLE KEY ENTRY RESET TIME AUTHORIZE**

- 1. Not Use
- 2. Use

**5. INPUT PORT PULL UP RESISTOR**

- K00     1. With Resistor                     2. Gate Direct
- K01     1. With Resistor                     2. Gate Direct
- K02     1. With Resistor                     2. Gate Direct
- K03     1. With Resistor                     2. Gate Direct
- K10     1. With Resistor                     2. Gate Direct
- K11     1. With Resistor                     2. Gate Direct
- K12     1. With Resistor                     2. Gate Direct
- K13     1. With Resistor                     2. Gate Direct

# CHAPTER 2 POWER SUPPLY AND INITIAL RESET

## 2.1 Power Supply

The E0C63567 operating power voltage is as follows:

Supply voltage  $V_{DD} = 2.2\text{ V to }5.5\text{ V}$

The E0C63567 operates by applying a single power supply within the above range between  $V_{DD}$  and  $V_{SS}$ . The E0C63567 itself generates the voltage necessary for all the internal circuits by the built-in power supply circuits shown in Table 2.1.1.

Table 2.1.1 Power supply circuits

Circuit	Power supply circuit	Output voltage
Oscillation and internal circuits	Oscillation system voltage regulator	$V_{D1}$
LCD driver	LCD system voltage circuit	$V_{C1}\text{--}V_{C5}$

- Note:
- Do not drive external loads with the output voltage from the internal power supply circuits.
  - See Chapter 7, "Electrical Characteristics", for voltage values and drive capability.

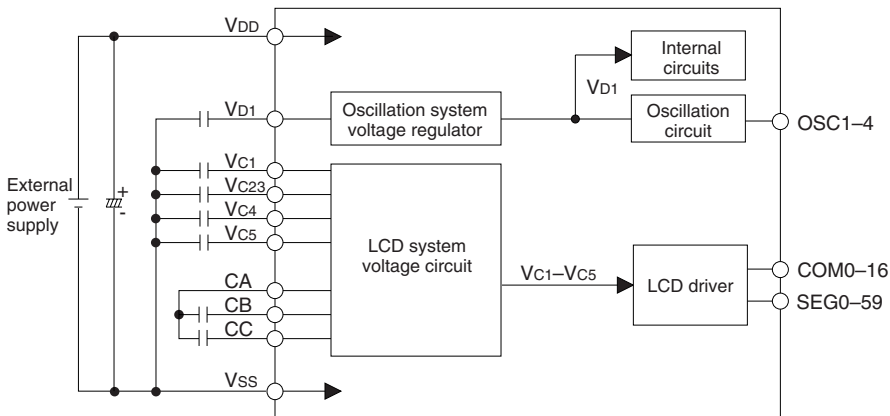

Fig. 2.1.1 Configuration of power supply

### 2.1.1 Voltage $\langle V_{D1} \rangle$ for oscillation circuit and internal circuits

$V_{D1}$  is a voltage for the oscillation circuit and the internal logic circuits, and is generated by the oscillation system voltage regulator for stabilizing the oscillation. The  $V_{D1}$  voltage is fixed at 2.1 V, so it is not necessary to control by software.

### 2.1.2 Voltage $\langle V_{C1}\text{--}V_{C5} \rangle$ for LCD driving

$V_{C1}$ ,  $V_{C23}$ ,  $V_{C4}$  and  $V_{C5}$  are the LCD (1/4 bias) drive voltages generated by the LCD system voltage circuit. These four output voltages can only be supplied to the externally expanded LCD driver. The LCD system voltage circuit generates  $V_{C23}$  with the voltage regulator built-in, and generates three other voltages by boosting or reducing the voltage of  $V_{C23}$ . Table 2.1.2.1 shows the  $V_{C1}$ ,  $V_{C23}$ ,  $V_{C4}$  and  $V_{C5}$  voltage values and boost/reduce status.

Table 2.1.2.1 LCD drive voltage when generated internally

LCD drive voltage	$V_{DD} = 2.2\text{ V to }2.5\text{ V}$	$V_{DD} = 2.5\text{ V to }5.5\text{ V}$
$V_{C1} = 1/2 \times V_{C23}$	$1/2 \times V_{C23}$	$1/2 \times V_{C23}$
$V_{C23} = (\text{standard})$	$(1.950\text{ to }2.4\text{ V}) \times (V_{DD}-0.1)/2.4$	1.950 to 2.4 V
$V_{C4} = 3/2 \times V_{C23}$	$3/2 \times V_{C23}$	$3/2 \times V_{C23}$
$V_{C5} = 2 \times V_{C23}$	$2 \times V_{C23}$	$2 \times V_{C23}$

Note: The LCD drive voltage can be adjusted by the software (see Section 4.7.5). Values in the above table are typical values.

Refer to Section 4.7, "LCD Driver", for control of the LCD drive voltage.

## 2.2 Initial Reset

To initialize the E0C63567 circuits, initial reset must be executed. There are two ways of doing this.

- (1) External initial reset by the  $\overline{\text{RESET}}$  terminal
- (2) External initial reset by simultaneous low input to terminals K00–K03 (mask option setting)

The circuits are initialized by either (1) or (2). When the power is turned on, be sure to initialize using the reset function. It is not guaranteed that the circuits are initialized by only turning the power on.

Figure 2.2.1 shows the configuration of the initial reset circuit.

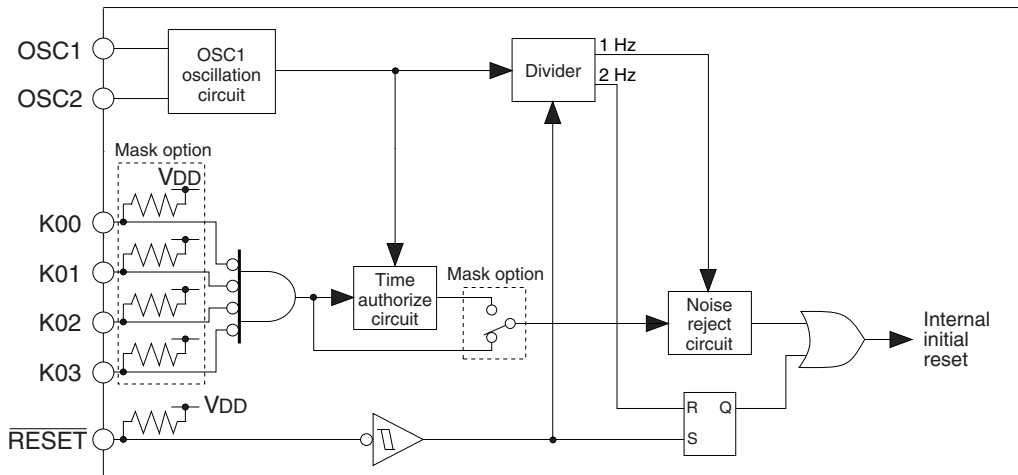

Fig. 2.2.1 Configuration of initial reset circuit

### 2.2.1 Reset terminal ( $\overline{\text{RESET}}$ )

Initial reset can be executed externally by setting the reset terminal to a low level ( $V_{SS}$ ). After that the initial reset is released by setting the reset terminal to a high level ( $V_{DD}$ ) and the CPU starts operating. The reset input signal is maintained by the RS latch and becomes the internal initial reset signal. The RS latch is designed to be released by a 2 Hz signal (high) that is divided by the OSC1 clock. Therefore in normal operation, a maximum of 250 msec (when  $f_{\text{OSC1}} = 32.768 \text{ kHz}$ ) is needed until the internal initial reset is released after the reset terminal goes to high level. Be sure to maintain a reset input of 0.1 msec or more.

However, when turning the power on, the reset terminal should be set at a low level as in the timing shown in Figure 2.2.1.1.

Fig. 2.2.1.1 Initial reset at power on

The reset terminal should be set to  $0.1 \cdot V_{DD}$  or less (low level) until the supply voltage becomes 2.2 V or more. After that, a level of  $0.5 \cdot V_{DD}$  or less should be maintained more than 2.0 msec.

### 2.2.2 Simultaneous low input to terminals K00–K03

Another way of executing initial reset externally is to input a low signal simultaneously to the input ports (K00–K03) selected with the mask option.

Since this initial reset passes through the noise reject circuit, maintain the specified input port terminals at low level for at least 1.5 msec (when the oscillation frequency  $f_{OSC1}$  is 32.768 kHz) during normal operation. The noise reject circuit does not operate immediately after turning the power on until the oscillation circuit starts oscillating. Therefore, maintain the specified input port terminals at low level for at least 1.5 msec (when the oscillation frequency  $f_{OSC1}$  is 32.768 kHz) after oscillation starts.

Table 2.2.2.1 shows the combinations of input ports (K00–K03) that can be selected with the mask option.

Table 2.2.2.1 Combinations of input ports

1	Not use
2	K00*K01*K02*K03
3	K00*K01*K02
4	K00*K01

When, for instance, mask option 2 (K00\*K01\*K02\*K03) is selected, initial reset is executed when the signals input to the four ports K00–K03 are all low at the same time. When 3 or 4 is selected, the initial reset is done when a key entry including a combination of selected input ports is made.

Further, the time authorize circuit can be selected with the mask option. The time authorize circuit checks the input time of the simultaneous low input and performs initial reset if that time is the defined time (1 to 2 sec) or more.

If using this function, make sure that the specified ports do not go low at the same time during ordinary operation.

### 2.2.3 Internal register at initial resetting

Initial reset initializes the CPU as shown in Table 2.2.3.1.

The registers and flags which are not initialized by initial reset should be initialized in the program if necessary.

In particular, the stack pointers SP1 and SP2 must be set as a pair because all the interrupts including NMI are masked after initial reset until both the SP1 and SP2 stack pointers are set with software.

When data is written to the EXT register, the E flag is set and the following instruction will be executed in the extended addressing mode. If an instruction which does not permit extended operation is used as the following instruction, the operation is not guaranteed. Therefore, do not write data to the EXT register for initialization only.

Refer to the "E0C63000 Core CPU Manual" for extended addressing and usable instructions.

Table 2.2.3.1 Initial values

CPU core				Peripheral circuits		
Name	Symbol	Number of bits	Setting value	Name	Number of bits	Setting value
Data register A	A	4	Undefined	RAM	4	Undefined
Data register B	B	4	Undefined	Display memory	4	Undefined

Stack pointer SP2	SP2	8	Undefined			
Zero flag	Z	1	Undefined			
Carry flag	C	1	Undefined			
Interrupt flag	I	1	0			
Extension flag	E	1	0			
Queue register	Q	16	Undefined			

\* See Section 4.1, "Memory Map".

## 2.2.4 Terminal settings at initial resetting

The output port (R) terminals and I/O port (P) terminals are shared with special output terminals and input/output terminals of the serial interface. These functions are selected by the software. At initial reset, these terminals are set to the general purpose output port terminals and I/O port terminals. Set them according to the system in the initial routine. In addition, take care of the initial status of output terminals when designing a system.

Table 2.2.4.1 shows the list of the shared terminal settings.

Table 2.2.4.1(a) List of shared terminal settings (Rxx)

Terminal name	Terminal status at initial reset	Special output							
		FOUT	TOUT	BZ	XBZ	HFO	HDO	XRMUTE	XTMUTE
R00	R00 (HIGH output)				XBZ				
R01	R01 (HIGH output)			BZ					
R02	R02 (HIGH output)		TOUT						
R03	R03 (HIGH output)	FOUT							
R10	R10 (HIGH output)								XTMUTE
R11	R11 (HIGH output)							XRMUTE	
R12	R12 (HIGH output)					HDO			
R13	R13 (HIGH output)					HFO			
R20–R23	R20–R23 (HIGH output)								

Table 2.2.4.1(b) List of shared terminal settings (Pxx)

Terminal name	Terminal status at initial reset	Special output		Serial I/F		
		CL	FR	Async.	Clk-sync. Master	Clk-sync. Slave
P00–P03	P00–P03 (Input & Pull-up *)					
P10	P10 (Input & Pull-up *)			SIN(I)	SIN(I)	SIN(I)
P11	P11 (Input & Pull-up *)			SOUT(O)	SOUT(O)	SOUT(O)
P12	P12 (Input & Pull-up *)				SCLK(O)	SCLK(I)
P13	P13 (Input & Pull-up *)					SRDY(O)
P20	P20 (Input & Pull-up *)					
P21	P21 (Input & Pull-up *)					
P22	P22 (Input & Pull-up *)	CL				
P23	P23 (Input & Pull-up *)		FR			
P30–P33	P30–P33 (Input & Pull-up *)					

\* When "with pull-up" is selected by mask option (high impedance when "gate direct" is selected)

For setting procedure of the functions, see explanations for each of the peripheral circuits.

## 2.3 Test Terminal ( $\overline{\text{TEST}}$ )

This is the terminal used for the factory inspection of the IC. During normal operation, connect the  $\overline{\text{TEST}}$  terminal to VDD.

# CHAPTER 3 CPU, ROM, RAM

## 3.1 CPU

The E0C63567 has a 4-bit core CPU E0C63000 built-in as its CPU part. Refer to the "E0C63000 Core CPU Manual" for the E0C63000.

*Note: The SLP instruction cannot be used because the SLEEP operation is not assumed in the E0C63567.*

## 3.2 Code ROM

The built-in code ROM is a mask ROM for loading programs, and has a capacity of 16,384 steps × 13 bits. The core CPU can linearly access the program space up to step FFFFH from step 0000H, however, the program area of the E0C63567 is step 0000H to step 3FFFH. The program start address after initial reset is assigned to step 0110H. The non-maskable interrupt (NMI) vector and hardware interrupt vectors are allocated to step 0100H and steps 0104H–010EH, respectively.

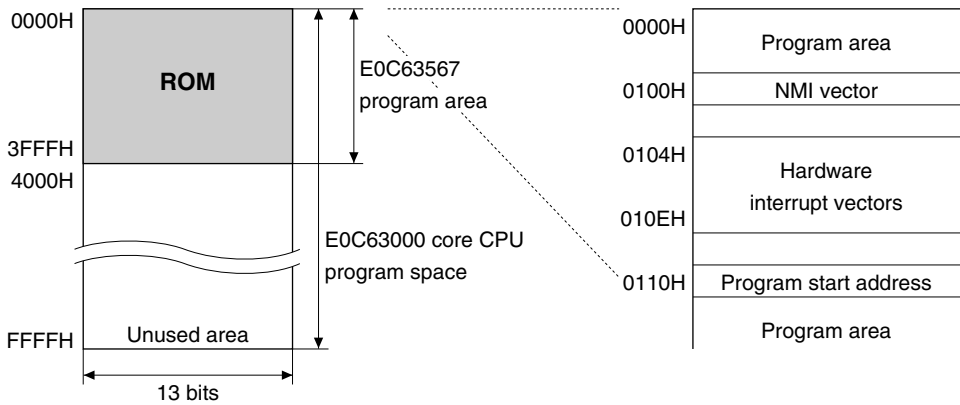

Fig. 3.2.1 Configuration of code ROM

## 3.3 RAM

The RAM is a data memory for storing various kinds of data, and has a capacity of 5,120 words × 4 bits. The RAM area is assigned to addresses 0000H to 13FFH on the data memory map. Addresses 0100H to 01FFH are 4-bit/16-bit data accessible areas and in other areas it is only possible to access 4-bit data. When programming, keep the following points in mind.

- (1) Part of the RAM area is used as a stack area for subroutine call and register evacuation, so pay attention not to overlap the data area and stack area.
- (2) The E0C63000 core CPU handles the stack using the stack pointer for 4-bit data (SP2) and the stack pointer for 16-bit data (SP1).  
 16-bit data are accessed in stack handling by SP1, therefore, this stack area should be allocated to the area where 4-bit/16-bit access is possible (0100H to 01FFH). The stack pointers SP1 and SP2 change cyclically within their respective range: the range of SP1 is 0000H to 03FFH and the range of SP2 is 0000H to 00FFH. Therefore, pay attention to the SP1 value because it may be set to 0200H or more exceeding the 4-bit/16-bit accessible range in the E0C63567 or it may be set to 00FFH or less. Memory accesses except for stack operations by SP1 are 4-bit data access.  
 After initial reset, all the interrupts including NMI are masked until both the stack pointers SP1 and SP2 are set by software. Further, if either SP1 or SP2 is re-set when both are set already, the interrupts including NMI are masked again until the other is re-set. Therefore, the settings of SP1 and SP2 must be done as a pair.

- (3) Subroutine calls use 4 words (for PC evacuation) in the stack area for 16-bit data (SP1). Interrupts use 4 words (for PC evacuation) in the stack area for 16-bit data (SP1) and 1 word (for F register evacuation) in the stack area for 4-bit data.

Fig. 3.3.1 Configuration of data RAM

### 3.4 Data ROM

The data ROM is a mask ROM for loading various static data such as a character generator, and has a capacity of 2,048 words  $\times$  4 bits. The data ROM is assigned to addresses 8000H to 87FFH on the data memory map, and the data can be read using the same data memory access instructions as the RAM.

# CHAPTER 4 PERIPHERAL CIRCUITS AND OPERATION

The peripheral circuits of E0C63567 (timer, I/O, etc.) are interfaced with the CPU in the memory mapped I/O method. Thus, all the peripheral circuits can be controlled by accessing the I/O memory on the memory map using the memory operation instructions. The following sections explain the detailed operation of each peripheral circuit.

## 4.1 Memory Map

The E0C63567 data memory consists of 5,120-word RAM, 2,048-word data ROM, 1,020-bit display memory and 84-word peripheral I/O memory. Figure 4.1.1 shows the overall memory map of the E0C63567, and Tables 4.1.1(a)-(g) the peripheral circuits' (I/O space) memory maps.

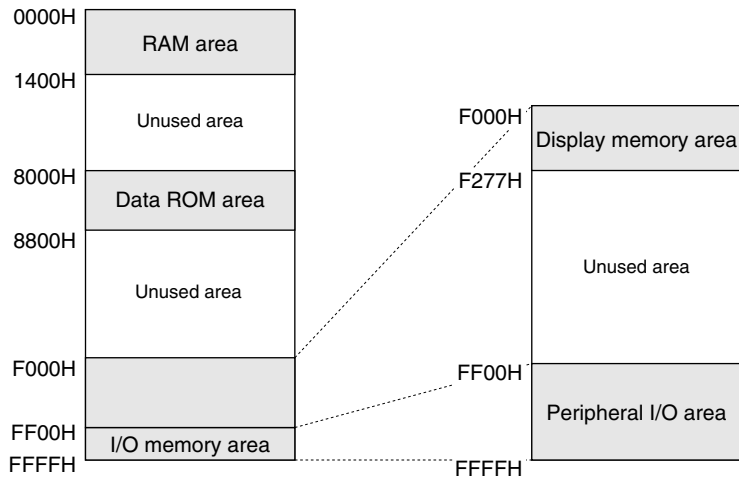

Fig. 4.1.1 Memory map

*Note: Memory is not implemented in unused areas within the memory map. Further, some non-implementation areas and unused (access prohibition) areas exist in the display memory area and the peripheral I/O area. If the program that accesses these areas is generated, its operation cannot be guaranteed. Refer to Section 4.7.4, "Display memory", for the display memory, and the I/O memory maps shown in Tables 4.1.1 (a)-(g) for the peripheral I/O area.*

Table 4.1.1 (a) I/O memory map (FF00H–FF18H)

## 4.2 Watchdog Timer

### 4.2.1 Configuration of watchdog timer

The E0C63567 has a built-in watchdog timer that operates with a 256 Hz divided clock from the OSC1 as the source clock. The watchdog timer starts operating after initial reset, however, it can be stopped by the software. The watchdog timer must be reset cyclically by the software while it operates. If the watchdog timer is not reset in at least 3–4 seconds, it generates a non-maskable interrupt (NMI) to the CPU.

Figure 4.2.1.1 is the block diagram of the watchdog timer.

Fig. 4.2.1.1 Watchdog timer block diagram

The watchdog timer contains a 10-bit binary counter, and generates the non-maskable interrupt when the last stage of the counter (0.25 Hz) overflows.

Watchdog timer reset processing in the program's main routine enables detection of program overrun, such as when the main routine's watchdog timer processing is bypassed. Ordinarily this routine is incorporated where periodic processing takes place, just as for the timer interrupt routine.

The watchdog timer operates in the HALT mode. If a HALT status continues for 3–4 seconds, the non-maskable interrupt releases the HALT status.

### 4.2.2 Interrupt function

If the watchdog timer is not reset periodically, the non-maskable interrupt (NMI) is generated to the core CPU. Since this interrupt cannot be masked, it is accepted even in the interrupt disable status (I flag = "0"). However, it is not accepted when the CPU is in the interrupt mask state until SP1 and SP2 are set as a pair, such as after initial reset or during re-setting the stack pointer. The interrupt vector of NMI is assigned to 0100H in the program memory.

### 4.2.3 I/O memory of watchdog timer

Table 4.2.3.1 shows the I/O address and control bits for the watchdog timer.

Table 4.2.3.1 Control bits of watchdog timer

Address	Register				Name	Init *1	1	0	Comment
	D3	D2	D1	D0					
FF07H	0	0	WDEN	WDRST	0 *3	- *2			Unused
					0 *3	- *2			Unused
	R		R/W	W	WDEN	1	Enable	Disable	Watchdog timer enable
				WDRST*3	Reset	Reset	Invalid		Watchdog timer reset (writing)

\*1 Initial value at initial reset

\*2 Not set in the circuit

\*3 Constantly "0" when being read

#### WDEN: Watchdog timer enable register (FF07H•D1)

Selects whether the watchdog timer is used (enabled) or not (disabled).

When "1" is written: Enabled

When "0" is written: Disabled

Reading: Valid

When "1" is written to the WDEN register, the watchdog timer starts count operation. When "0" is written, the watchdog timer does not count and does not generate the interrupt (NMI).

At initial reset, this register is set to "1".

#### WDRST: Watchdog timer reset (FF07H•D0)

Resets the watchdog timer.

When "1" is written: Watchdog timer is reset

When "0" is written: No operation

Reading: Always "0"

When "1" is written to WDRST, the watchdog timer is reset and restarts immediately after that. When "0" is written, no operation results.

This bit is dedicated for writing, and is always "0" for reading.

### 4.2.4 Programming notes

- (1) When the watchdog timer is being used, the software must reset it within 3-second cycles.
- (2) Because the watchdog timer is set in operation state by initial reset, set the watchdog timer to disabled state (not used) before generating an interrupt (NMI) if it is not used.

### 4.3 Oscillation Circuit

#### 4.3.1 Configuration of oscillation circuit

The E0C63567 has two oscillation circuits (OSC1 and OSC3). OSC1 is either a crystal or a CR oscillation circuit that supplies the operating clock to the CPU and peripheral circuits. OSC3 is either a CR or a ceramic oscillation circuit. When processing with the E0C63567 requires high-speed operation, the CPU operating clock can be switched from OSC1 to OSC3 by the software. Figure 4.3.1.1 is the block diagram of this oscillation system.

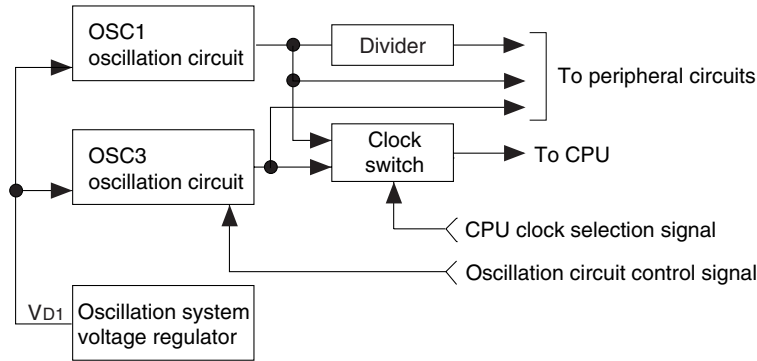

Fig. 4.3.1.1 Oscillation system block diagram

#### 4.3.2 OSC1 oscillation circuit

The OSC1 oscillation circuit generates the main clock for the CPU and the peripheral circuits. Either the crystal oscillation circuit or the CR oscillation circuit can be selected as the circuit type by mask option. The oscillation frequency of the crystal oscillation circuit is 32.768 kHz (Typ.) and the CR oscillation circuit is 60 kHz (Typ.).

Figure 4.3.2.1 is the block diagram of the OSC1 oscillation circuit.

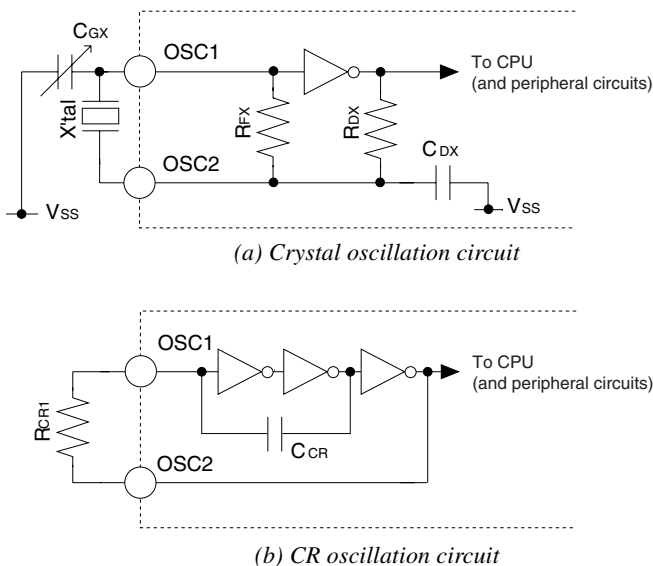

Fig. 4.3.2.1 OSC1 oscillation circuit

As shown in Figure 4.3.2.1, the crystal oscillation circuit can be configured simply by connecting the crystal oscillator (X'tal) of 32.768 kHz (Typ.) between the OSC1 and OSC2 terminals and the trimmer capacitor (CGX) between the OSC1 and VSS terminals when crystal oscillation is selected.

The CR oscillation circuit can be configured simply by connecting the resistor RCR1 between the OSC1 and OSC2 terminals when CR oscillation is selected. See Chapter 7, "Electrical Characteristics" for resistance value of RCR1.

*Note:*

- The current consumption of CR oscillation is larger than crystal oscillation.

- Be aware that the CR oscillation frequency changes slightly.

Pay special attention to the circuits that use *fosc1* as the source clock, such as the timer (time lag), the LCD frame frequency (display quality, flicker in low frequency) and the sound generator (sound quality).

### 4.3.3 OSC3 oscillation circuit

The E0C63567 has built-in the OSC3 oscillation circuit that generates the CPU's sub-clock (3.58 MHz) for high speed operation and the source clock for peripheral circuits needing a high speed clock (programmable timer, FOUT output). The mask option enables selection of either the CR or ceramic oscillation circuit. When CR oscillation is selected, only a resistance is required as an external element. When ceramic oscillation is selected, a ceramic oscillator and two capacitors (gate and drain capacitance) are required.

Figure 4.3.3.1 is the block diagram of the OSC3 oscillation circuit.

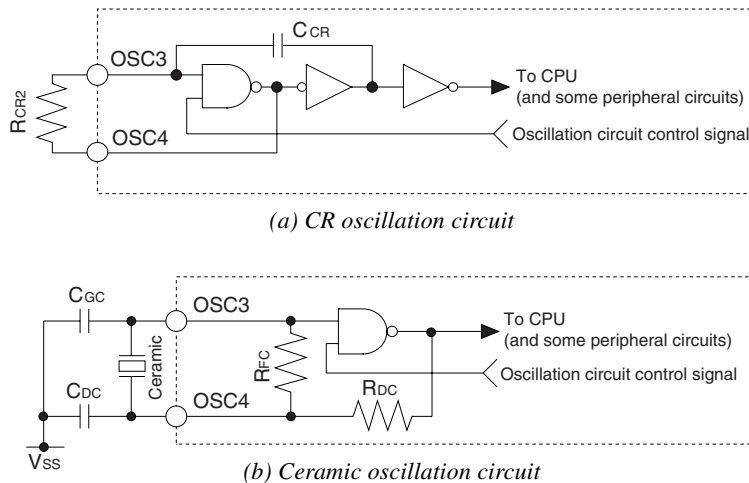

Fig. 4.3.3.1 OSC3 oscillation circuit

As shown in Figure 4.3.3.1, the CR oscillation circuit can be configured simply by connecting the resistor RCR2 between the OSC3 and OSC4 terminals when CR oscillation is selected. See Chapter 7, "Electrical Characteristics" for resistance value of RCR2.

When ceramic oscillation is selected, the ceramic oscillation circuit can be configured by connecting the ceramic oscillator (3.58 MHz) between the OSC3 and OSC4 terminals, capacitor CGC between the OSC3 and OSC4 terminals, and capacitor CDC between the OSC4 and VSS terminals. For both CGC and CDC, connect capacitors that are about 30 pF. To reduce current consumption of the OSC3 oscillation circuit, oscillation can be stopped by the software (OSCC register).

### 4.3.4 Switching the CPU operating clock

The CPU system clock is switched to OSC1 or OSC3 by the software (CLKCHG register). When OSC3 is to be used as the CPU system clock, first turn the OSC3 oscillation ON and switch the clock after waiting 5 msec or more for oscillation stabilization.

When switching from OSC3 to OSC1, turn the OSC3 oscillation circuit OFF after switching the clock.

**OSC1 → OSC3**

1. Set OSCC to "1" (OSC3 oscillation ON).
2. Maintain 5 msec or more.
3. Set CLKCHG to "1" (OSC1 → OSC3).

**OSC3 → OSC1**

1. Set CLKCHG to "0" (OSC3 → OSC1).
2. Set OSCC to "0" (OSC3 oscillation OFF).

*Note:* When switching the clock form OSC3 to OSC1, use a separate instruction for switching the OSC3 oscillation OFF. An error in the CPU operation can result if this processing is performed at the same time by the one instruction.

### 4.3.5 Clock frequency and instruction execution time

Table 4.3.5.1 shows the instruction execution time according to each frequency of the system clock.

Table 4.3.5.1 Clock frequency and instruction execution time

Clock frequency	Instruction execution time (μsec)		
	1-cycle instruction	2-cycle instruction	3-cycle instruction
OSC1: 32.768 kHz	61	122	183
OSC1: 60 kHz	33	67	100
OSC3: 3.58 MHz	0.56	1.12	1.68

### 4.3.6 I/O memory of oscillation circuit

Table 4.3.6.1 shows the I/O address and the control bits for the oscillation circuit.

Table 4.3.6.1 Control bits of oscillation circuit

Address	Register								Comment
	D3	D2	D1	D0	Name	Init *1	1	0	
FF00H	CLKCHG	OSCC	0	Dummy	CLKCHG	0	OSC3	OSC1	CPU clock switch
					OSCC	0	On	Off	OSC3 oscillation On/Off
					0 *3	- *2			Unused
		R/W	R	R/W	Dummy	0			General-purpose register

\*1 Initial value at initial reset

\*2 Not set in the circuit

\*3 Constantly "0" when being read

**OSCC: OSC3 oscillation control register (FF00H•D2)**

Controls oscillation ON/OFF for the OSC3 oscillation circuit.

When "1" is written: OSC3 oscillation ON

When "0" is written: OSC3 oscillation OFF

Reading: Valid

When it is necessary to operate the CPU at high speed, set OSCC to "1". At other times, set it to "0" to reduce current consumption.

At initial reset, this register is set to "0".

**CLKCHG: CPU system clock switching register (FF00H•D3)**

The CPU's operation clock is selected with this register.

When "1" is written: OSC3 clock is selected

When "0" is written: OSC1 clock is selected

Reading: Valid

When the CPU clock is to be OSC3, set CLKCHG to "1"; for OSC1, set CLKCHG to "0".

After turning the OSC3 oscillation ON (OSCC = "1"), switching of the clock should be done after waiting 5 msec or more.

At initial reset, this register is set to "0".

**4.3.7 Programming notes**

- (1) It takes at least 5 msec from the time the OSC3 oscillation circuit goes ON until the oscillation stabilizes. Consequently, when switching the CPU operation clock from OSC1 to OSC3, do this after a minimum of 5 msec have elapsed since the OSC3 oscillation went ON.  
Further, the oscillation stabilization time varies depending on the external oscillator characteristics and conditions of use, so allow ample margin when setting the wait time.
- (2) When switching the clock from OSC3 to OSC1, use a separate instruction for switching the OSC3 oscillation OFF. An error in the CPU operation can result if this processing is performed at the same time by the one instruction.
- (3) The internal operating voltage of VD1 is fixed at 2.1 V. So it is not necessary to control the operating voltage regardless of the operating clock selected.

## 4.4 Input Ports (K00–K03 and K10–K13)

### 4.4.1 Configuration of input ports

The E0C63567 has eight bits general-purpose input ports. Each of the input port terminals (K00–K03, K10–K13) provides internal pull-up resistor. Pull-up resistor can be selected for each bit with the mask option.

Figure 4.4.1.1 shows the configuration of input port.

Fig. 4.4.1.1 Configuration of input port

Selection of "With pull-up resistor" with the mask option suits input from the push switch, key matrix, and so forth. When "Gate direct" is selected, the port can be used for slide switch input and interfacing with other LSIs.

### 4.4.2 Interrupt function

All eight bits of the input ports (K00–K03, K10–K13) provide the interrupt function. The conditions for issuing an interrupt can be set by the software. Further, whether to mask the interrupt function can be selected by the software.

Figure 4.4.2.1 shows the configuration of K00–K03 (K10–K13) interrupt circuit.

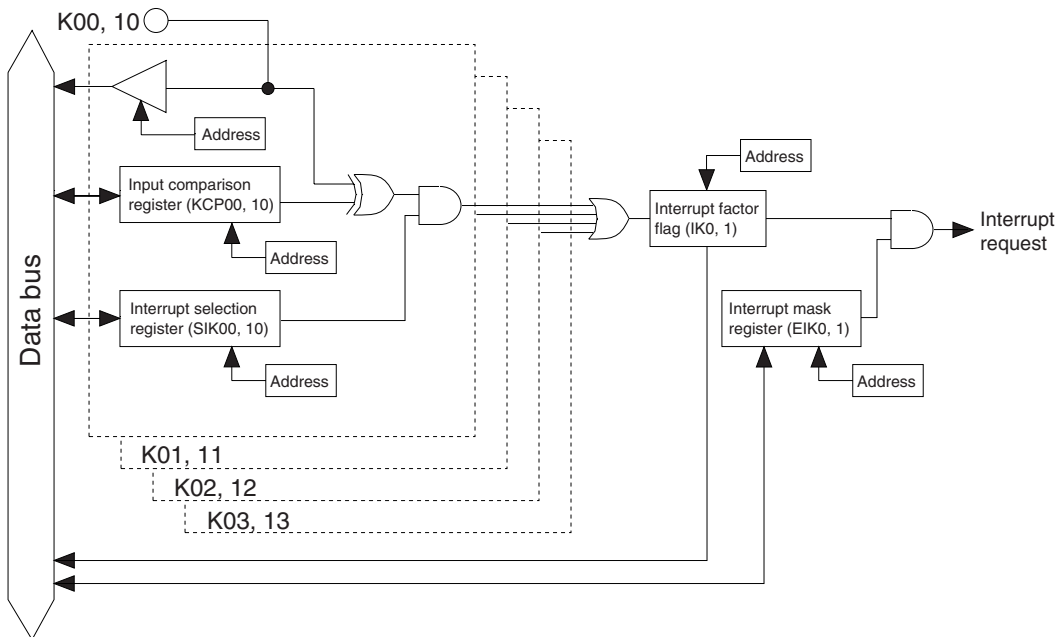

Fig. 4.4.2.1 Input interrupt circuit configuration

The interrupt selection register (SIK) and input comparison register (KCP) are individually set for the input ports K00–K03 and K10–K13, and can specify the terminals for generating interrupt and interrupt timing.

The interrupt selection registers (SIK00–SIK03, SIK10–SIK13) select what input of K00–K03 and K10–K13 to use for the interrupt. Writing "1" into an interrupt selection register incorporates that input port into the interrupt generation conditions. The changing the input port where the interrupt selection register has been set to "0" does not affect the generation of the interrupt.

The input interrupt timing can select that the interrupt be generated at the rising edge of the input or that it be generated at the falling edge according to the set value of the input comparison registers (KCP00–KCP03, KCP10–KCP13).

By setting these two conditions, the interrupt for K00–K03 or K10–K13 is generated when input ports in which an interrupt has been enabled by the input selection registers and the contents of the input comparison registers have been changed from matching to no matching.

The interrupt mask registers (EIK0, EIK1) enable the interrupt mask to be selected for K00–K03 and K10–K13.

When the interrupt is generated, the interrupt factor flag (IK0, IK1) is set to "1".

Figure 4.4.2.2 shows an example of an interrupt for K00–K03.

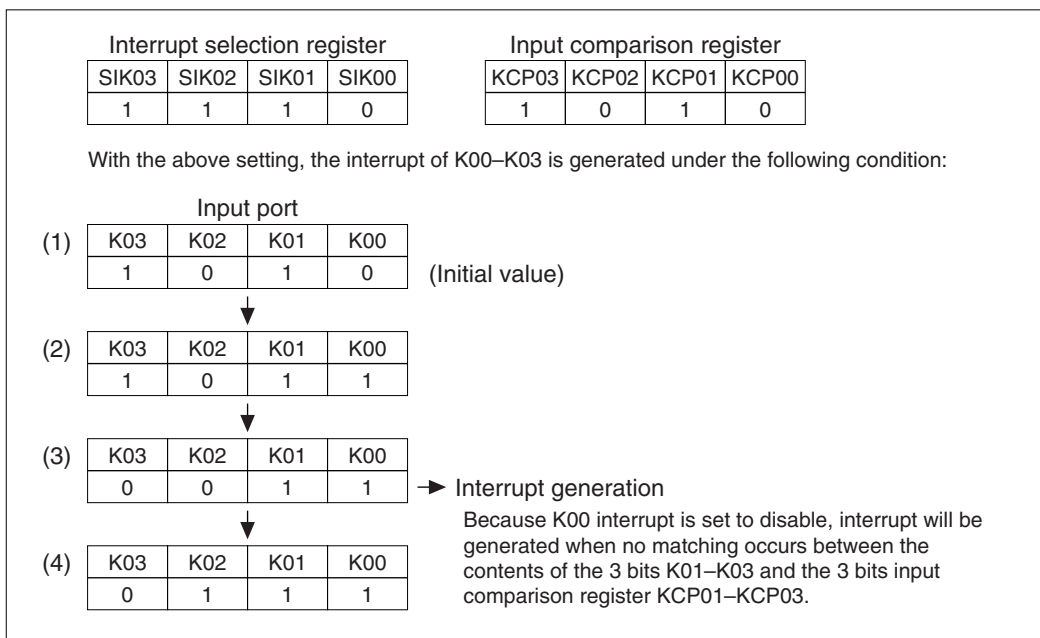

Fig. 4.4.2.2 Example of interrupt of K00–K03

K00 interrupt is disabled by the interrupt selection register (SIK00), so that an interrupt does not occur at (2). At (3), K03 changes to "0"; the data of the terminals that are interrupt enabled no longer match the data of the input comparison registers, so that interrupt occurs. As already explained, the condition for the interrupt to occur is the change in the port data and contents of the input comparison registers from matching to no matching. Hence, in (4), when the no matching status changes to another no matching status, an interrupt does not occur. Further, terminals that have been masked for interrupt do not affect the conditions for interrupt generation.

#### 4.4.3 Mask option

Internal pull-up resistor can be selected for each of the eight bits of the input ports (K00–K03, K10–K13) with the input port mask option.

When "Gate direct" is selected, take care that the floating status does not occur for the input. Select "With pull-up resistor" for input ports that are not being used.

### 4.4.4 I/O memory of input ports

Table 4.4.4.1 shows the I/O addresses and the control bits for the input ports.

Table 4.4.4.1 Control bits of input ports

Address	Register				Name	Init *1	1	0	Comment

				R/W	IK1	0	Reset	Invalid	Interrupt factor flag (K10–K13)

\*1 Initial value at initial reset

\*2 Not set in the circuit

\*3 Constantly "0" when being read

#### K00–K03: K0 port input port data (FF21H)

#### K10–K13: K1 port input port data (FF25H)

Input data of the input port terminals can be read with these registers.

When "1" is read: High level

When "0" is read: Low level

Writing: Invalid

The reading is "1" when the terminal voltage of the eight bits of the input ports (K00–K03, K10–K13) goes high (VDD), and "0" when the voltage goes low (VSS).

These bits are dedicated for reading, so writing cannot be done.

**SIK00–SIK03: K0 port interrupt selection register (FF20H)****SIK10–SIK13: K1 port interrupt selection register (FF24H)**

Selects the ports to be used for the K00–K03 and K10–K13 input interrupts.

When "1" is written: Enable  
 When "0" is written: Disable  
 Reading: Valid

Enables the interrupt for the input ports (K00–K03, K10–K13) for which "1" has been written into the interrupt selection registers (SIK00–SIK03, SIK10–SIK13). The input port set for "0" does not affect the interrupt generation condition.

At initial reset, these registers are set to "0".

**KCP00–KCP03: K0 port input comparison register (FF22H)****KCP10–KCP13: K1 port input comparison register (FF26H)**

Interrupt conditions for terminals K00–K03 and K10–K13 can be set with these registers.

When "1" is written: Falling edge  
 When "0" is written: Rising edge  
 Reading: Valid

The interrupt conditions can be set for the rising or falling edge of input for each of the eight bits (K00–K03 and K10–K13), through the input comparison registers (KCP00–KCP03 and KCP10–KCP13). For KCP00–KCP03, a comparison is done only with the ports that are enabled by the interrupt among K00–K03 by means of the SIK00–SIK03 registers. For KCP10–KCP13, a comparison is done only with the ports that are enabled by the interrupt among K10–K13 by means of the SIK10–SIK13 registers.

At initial reset, these registers are set to "1".

**EIK0: K0 input interrupt mask register (FFE4H•D0)****EIK1: K1 input interrupt mask register (FFE5H•D0)**

Masking the interrupt of the input port can be selected with these registers.

When "1" is written: Enable  
 When "0" is written: Mask  
 Reading: Valid

With these registers, masking of the input port interrupt can be selected for each of the two systems (K00–K03, K10–K13).

At initial reset, these registers are set to "0".

**IK0: K0 input interrupt factor flag (FFF4H•D0)****IK1: K1 input interrupt factor flag (FFF5H•D0)**

These flags indicate the occurrence of input interrupt.

When "1" is read: Interrupt has occurred  
 When "0" is read: Interrupt has not occurred

When "1" is written: Flag is reset  
 When "0" is written: Invalid

The interrupt factor flags IK0 and IK1 are associated with K00–K03 and K10–K13, respectively. From the status of these flags, the software can decide whether an input interrupt has occurred.

The interrupt factor flag is set to "1" when the interrupt condition is established regardless of the interrupt mask register setting. However, the interrupt does not occur to the CPU when the interrupt is masked.

These flags are reset to "0" by writing "1" to them.

After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.

At initial reset, these flags are set to "0".

### 4.4.5 Programming notes

- (1) When input ports are changed from low to high by pull-up resistors, the rise of the waveform is delayed on account of the time constant of the pull-up resistor and input gate capacitance. Hence, when fetching input ports, set an appropriate waiting time.

Particular care needs to be taken of the key scan during key matrix configuration.

Make this waiting time the amount of time or more calculated by the following expression.

$$10 \times C \times R$$

C: terminal capacitance 5 pF + parasitic capacitance ? pF

R: pull-up resistance 330 k $\Omega$

- (2) The K13 terminal functions as the clock input terminal for the programmable timer, and the input signal is shared with the input port and the programmable timer. Therefore, when the K13 terminal is set to the clock input terminal for the programmable timer, take care of the interrupt setting.
- (3) After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.

## 4.5 Output Ports (R00–R03, R10–R13 and R20–R23)

### 4.5.1 Configuration of output ports

The E0C63567 has 12 bits general output ports.

Output specifications of the output ports can be selected individually with the mask option. Two kinds of output specifications are available: complementary output and N-channel open drain output.

Figure 4.5.1.1 shows the configuration of the output port.

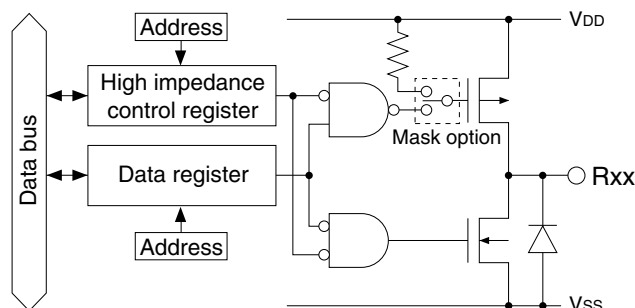

Fig. 4.5.1.1 Configuration of output port

The R00 to R03 output terminals are shared with the buzzer/clock outputs (XBZ, BZ, TOUT, FOUT). The R10 to R13 output terminals are shared with the tone/pulse dialer outputs (XTMUTE, XRMUTE, HDO, HFO). These functions are selected by the software.

At initial reset, these are all set to the general purpose output port.

Table 4.5.1.1 shows the setting of the output terminals by function selection.

Table 4.5.1.1 Function setting of output terminals

Terminal name	Terminal status at initial reset	Special output							
		FOUT	TOUT	BZ	XBZ	HFO	HDO	XRMUTE	XTMUTE
R00	R00 (HIGH output)	R00	R00	R00	XBZ	R00	R00	R00	R00
R01	R01 (HIGH output)	R01	R01	BZ	R01	R01	R01	R01	R01
R02	R02 (HIGH output)	R02	TOUT	R02	R02	R02	R02	R02	R02
R03	R03 (HIGH output)	FOUT	R03	R03	R03	R03	R03	R03	R03
R10	R10 (HIGH output)	R10	R10	R10	R10	R10	R10	R10	XTMUTE
R11	R11 (HIGH output)	R11	R11	R11	R11	R11	R11	XRMUTE	R11
R12	R12 (HIGH output)	R12	R12	R12	R12	R12	HDO	R12	R12
R13	R13 (HIGH output)	R13	R13	R13	R13	HFO	R13	R13	R13
R20–R23	R20–R23 (HIGH output)	R20–R23	R20–R23	R20–R23	R20–R23	R20–R23	R20–R23	R20–R23	R20–R23

When using the output port as the special output port, the data register must be fixed at "1" and the high impedance control register must be fixed at "0" (data output).

### 4.5.2 Mask option

Output specifications of the output ports can be selected with the mask option.

Either complementary output or N-channel open drain output can be selected individually (1-bit units).

However, when N-channel open drain output is selected, do not apply a voltage exceeding the power supply voltage to the output port.

### 4.5.3 High impedance control

The terminal output status of the output ports can be set to a high impedance status. This control is done using the high impedance control register (RxxHIZ) corresponding to each output port (Rxx). When "1" is written to the high impedance control register, the corresponding output port terminal goes into high impedance status. When "0" is written, the port outputs a signal according to the data register.

### 4.5.4 Special output

In addition to the regular DC output, special output can be selected for the output ports R00–R03 and R10–R13 as shown in Table 4.5.4.1 with the software.

Figure 4.5.4.1 shows the configuration of the R00–R03 and R10–R13 output ports.

Table 4.5.4.1 Special output

Terminal	Special output	Output control register
R13	HFO	CHFO
R12	HDO	CHDO
R11	XRMUTE	CRMO
R10	XTMUTE	CTMO
R03	FOUT	FOUTE
R02	TOUT	PTOUT
R01	BZ	BZOUT
R00	XBZ	XBZOUT

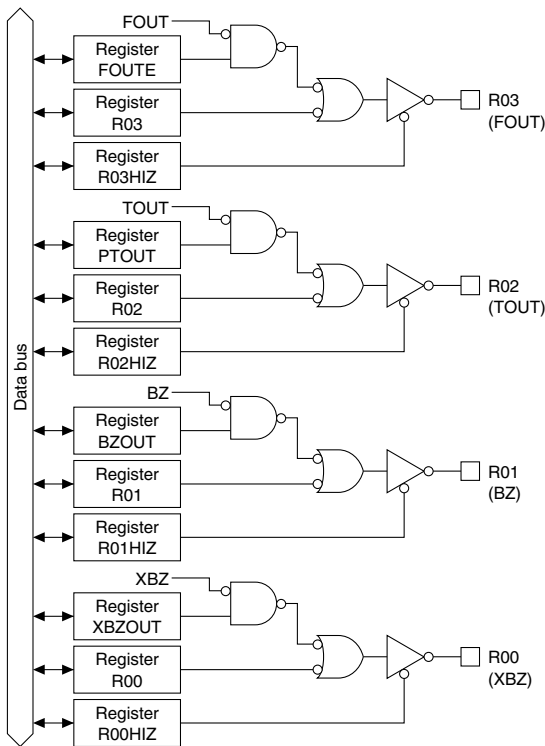

Fig. 4.5.4.1(a) Configuration of R00–R03 output ports

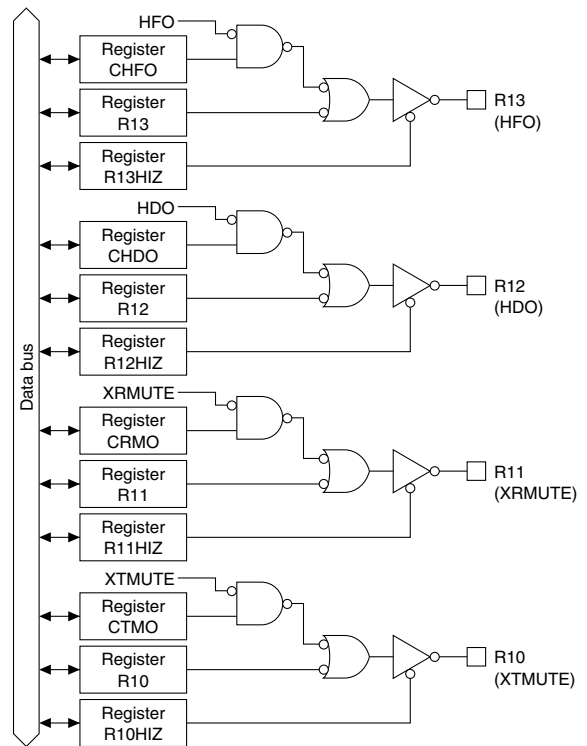

Fig. 4.5.4.1(b) Configuration of R10–R13 output ports

At initial reset, the output port data register is set to "1" and the high impedance control register is set to "0". Consequently, the output terminal goes high (VDD).

When using the output port (R00–R03, R10–R13) as the special output port, fix the data register (R00–R03, R10–R13) at "1" and the high impedance control register (R00HIZ–R03HIZ, R10HIZ–R13HIZ) at "0" (data output). The respective signal should be turned ON and OFF using the special output control register.

- Note:
- Be aware that the output terminal is fixed at a low (Vss) level the same as the DC output if "0" is written to the R00–R03 and R10–R13 registers when the special output has been selected.
  - Be aware that the output terminal shifts into high impedance status when "1" is written to the high impedance control register (R00HIZ–R03HIZ, R10HIZ–R13HIZ).
  - A hazard may occur when the special output signal is turned ON and OFF by software.

#### • XBZ (R00)

The R00 terminal can output an XBZ signal.

The XBZ signal is the buzzer inverted signal that is output from the sound generator, and can be used to drive a piezoelectric buzzer with the BZ signal.

To output the XBZ signal, set the R00 port as the XBZ output by writing "1" to the XBZOUT register and fix the R00 register at "1" and the R00HIZ register at "0". Use the BZE register for controlling (ON/OFF) the XBZ signal output.

Refer to Section 4.12, "Sound Generator" for details of the buzzer signal and controlling method.

#### • BZ (R01)

The R01 terminal can output a BZ signal.

The BZ signal is the buzzer signal that is output from the sound generator.

To output the BZ signal, set the R01 port as the BZ output by writing "1" to the BZOUT register and fix the R01 register at "1" and the R01HIZ register at "0". Use the BZE register for controlling (ON/OFF) the BZ signal output.

Refer to Section 4.12, "Sound Generator" for details of the buzzer signal and controlling method.

#### • TOUT (R02)

The R02 terminal can output a TOUT signal.

The TOUT signal is the clock that is output from the programmable timer, and can be used to provide a clock signal to an external device.

To output the TOUT signal, fix the R02 register at "1" and the R02HIZ register at "0", and turn the signal ON and OFF using the PTOUT register. It is, however, necessary to control the programmable timer.

Refer to Section 4.10, "Programmable Timer" for details of the TOUT signal and controlling method.

#### • FOUT (R03)

The R03 terminal can output an FOUT signal.

The FOUT signal is a clock (fOSC1 or fOSC3) that is output from the oscillation circuit or a clock that the fOSC1 clock has divided in the internal circuit, and can be used to provide a clock signal to an external device.

To output the FOUT signal, fix the R03 register at "1" and the R03HIZ register at "0", and turn the signal ON and OFF using the FOUTE register.

The frequency of the output clock may be selected from among 4 types shown in Table 4.5.4.2 by setting the FOFQ0 and FOFQ1 registers.

Table 4.5.4.2 FOUT clock frequency

FOFQ1	FOFQ0	Clock frequency
1	1	fOSC3
1	0	fOSC1
0	1	fOSC1 × 1/8
0	0	fOSC1 × 1/64

fOSC1: Clock that is output from the OSC1 oscillation circuit

fOSC3: Clock that is output from the OSC3 oscillation circuit

When fOSC3 is selected for the FOUT signal frequency, it is necessary to control the OSC3 oscillation circuit before output.

Refer to Section 4.3, "Oscillation Circuit", for the control and notes.

Figure 4.5.4.2 shows the output waveform of the FOUT signal.

Fig. 4.5.4.2 Output waveform of FOUT signal

• **XTMUTE (R10)**

The R10 terminal can output an XTMUTE signal.

The XTMUTE signal is the transmitter mute signal used for the telephone function.

To output the XTMUTE signal, set the R10 port as the XTMUTE output by writing "1" to the CTMO register and fix the R10 register at "1" and the R10HIZ register at "0". Use the CTMUTE register for controlling the XTMUTE signal output.

Refer to Section 4.14, "Telephone Function" for details of the signal and controlling method.

• **XRMUTE (R11)**

The R11 terminal can output an XRMUTE signal.

The XRMUTE signal is the receiver mute signal used for the telephone function.

To output the XRMUTE signal, set the R11 port as the XRMUTE output by writing "1" to the CRMO register and fix the R11 register at "1" and the R11HIZ register at "0". Use the CRMUTE register for controlling the XRMUTE signal output.

Refer to Section 4.14, "Telephone Function" for details of the signal and controlling method.

• **HDO (R12)**

The R12 terminal can output a HDO signal.

The HDO signal is the hold line signal used for the telephone function.

To output the HDO signal, set the R12 port as the HDO output by writing "1" to the CHDO register and fix the R12 register at "1" and the R12HIZ register at "0". Use the HOLD register for controlling the HDO signal output.

Refer to Section 4.14, "Telephone Function" for details of the signal and controlling method.

• **HFO (R13)**

The R13 terminal can output a HFO signal.

The HFO signal is the hand free signal used for the telephone function.

To output the HFO signal, set the R13 port as the HFO output by writing "1" to the CHFO register and fix the R13 register at "1" and the R13HIZ register at "0". Use the HF register for controlling the HFO signal output.

Refer to Section 4.14, "Telephone Function" for details of the signal and controlling method.

## 4.5.5 I/O memory of output ports

Table 4.5.5.1 shows the I/O addresses and control bits for the output ports.

Table 4.5.5.1 Control bits of output ports

Address	Register				Comment

\*1 Initial value at initial reset

\*2 Not set in the circuit

\*3 Constantly "0" when being read

**R00HIZ–R03HIZ: R0 port high impedance control register (FF30H)**

**R10HIZ–R13HIZ: R1 port high impedance control register (FF32H)**

**R20HIZ–R23HIZ: R2 port high impedance control register (FF34H)**

Controls high impedance output of the output port.

When "1" is written: High impedance

When "0" is written: Data output

Reading: Valid

By writing "0" to the high impedance control register, the corresponding output terminal outputs according to the data register. When "1" is written, it shifts into high impedance status.

When an output port (R00–R03, R10–R13) is used for special output, fix the corresponding high impedance control register at "0" (data output).

At initial reset, these registers are set to "0".

**R00–R03: R0 output port data register (FF31H)**

**R10–R13: R1 output port data register (FF33H)**

**R20–R23: R2 output port data register (FF35H)**

Set the output data for the output ports.

When "1" is written: High level output

When "0" is written: Low level output

Reading: Valid

The output port terminals output the data written in the corresponding data registers without changing it. When "1" is written to the register, the output port terminal goes high (VDD), and when "0" is written, the output port terminal goes low (VSS).

When an output port (R00–R03, R10–R13) is used for special output, fix the corresponding data register at "1".

At initial reset, these registers are all set to "1".

**XBZOUT: R00 output selection register (FF65H•D0)**

Selects the R00 terminal function.

When "1" is written: XBZ output

When "0" is written: General-purpose DC output

Reading: Valid

When using the R00 terminal for the XBZ output, write "1" to this register. Furthermore, fix the R00 register at "1" and the R00HIZ register at "0". Refer to Section 4.12, "Sound Generator", for controlling the XBZ output.

When using the R00 output port for a general-purpose output, fix this register at "0".

At initial reset, this register is set to "0".

**BZOUT: R01 output selection register (FF65H•D1)**

Selects the R01 terminal function.

When "1" is written: BZ output

When "0" is written: General-purpose DC output

Reading: Valid

When using the R01 terminal for the BZ output, write "1" to this register. Furthermore, fix the R01 register at "1" and the R01HIZ register at "0". Refer to Section 4.12, "Sound Generator", for controlling the BZ output.

When using the R01 output port for a general-purpose output, fix this register at "0".

At initial reset, this register is set to "0".

**PTOUT: TOUT output control register (FFC1H•D2)**

Controls the TOUT output.

When "1" is written: TOUT output ON

When "0" is written: TOUT output OFF

Reading: Valid

By writing "1" to the PTOUT register when the R02 register has been set to "1" and the R02HIZ register has been set to "0", the TOUT signal is output from the R02 terminal. When "0" is written, the R02 terminal goes high (VDD).

When using the R02 output port for general-purpose output, fix this register at "0".

At initial reset, this register is set to "0".

**FOUTE: FOUT output control register (FF06H•D3)**

Controls the FOUT output.

When "1" is written: FOUT output ON

When "0" is written: FOUT output OFF

Reading: Valid

By writing "1" to the FOUTE register when the R03 register has been set to "1" and the R03HIZ register has been set to "0", an FOUT signal is output from the R03 terminal. When "0" is written, the R03 terminal goes high (VDD).

When using the R03 output port for general-purpose output, fix this register at "0".

At initial reset, this register is set to "0".

**FOFQ0, FOFQ1: FOUT frequency selection register (FF06H•D0, D1)**

Selects a frequency of the FOUT signal.

*Table 4.5.5.2 FOUT clock frequency*

FOFQ1	FOFQ0	Clock frequency
1	1	fosc3
1	0	fosc1
0	1	fosc1 × 1/8
0	0	fosc1 × 1/64

At initial reset, this register is set to "0".

**CTMO: R10 output selection register (FF13H•D0)**

Selects the R10 terminal function.

When "1" is written: XTMUTE output

When "0" is written: General-purpose DC output

Reading: Valid

When using the R10 terminal for the XTMUTE output, write "1" to this register. Furthermore, fix the R10 register at "1" and the R10HIZ register at "0". Refer to Section 4.14, "Telephone Function", for controlling the XTMUTE output.

When using the R10 output port for a general-purpose output, fix this register at "0".

At initial reset, this register is set to "0".

**CRMO: R11 output selection register (FF13H•D1)**

Selects the R11 terminal function.

When "1" is written: XRMUTE output

When "0" is written: General-purpose DC output

Reading: Valid

When using the R11 terminal for the XRMUTE output, write "1" to this register. Furthermore, fix the R11 register at "1" and the R11HIZ register at "0". Refer to Section 4.14, "Telephone Function", for controlling the XRMUTE output.

When using the R11 output port for a general-purpose output, fix this register at "0".

At initial reset, this register is set to "0".

**CHDO: R12 output selection register (FF13H•D2)**

Selects the R12 terminal function.

When "1" is written: HDO output

When "0" is written: General-purpose DC output

Reading: Valid

When using the R12 terminal for the HDO output, write "1" to this register. Furthermore, fix the R12 register at "1" and the R12HIZ register at "0". Refer to Section 4.14, "Telephone Function", for controlling the HDO output.

When using the R12 output port for a general-purpose output, fix this register at "0".

At initial reset, this register is set to "0".

**CHFO: R13 output selection register (FF13H•D3)**

Selects the R13 terminal function.

When "1" is written: HFO output

When "0" is written: General-purpose DC output

Reading: Valid

When using the R13 terminal for the HFO output, write "1" to this register. Furthermore, fix the R13 register at "1" and the R13HIZ register at "0". Refer to Section 4.14, "Telephone Function", for controlling the HFO output.

When using the R13 output port for a general-purpose output, fix this register at "0".

At initial reset, this register is set to "0".

**4.5.6 Programming notes**

(1) When using an output port (R00–R03, R10–R13) for special output, fix the corresponding data register (R00–R03, R10–R13) at "1" and the high impedance control register (R00HIZ–R03HIZ, R10HIZ–R13HIZ) at "0" (data output).

Be aware that the output terminal is fixed at a low (Vss) level the same as the DC output if "0" is written to the data registers when the special output has been selected.

Be aware that the output terminal shifts into high impedance status when "1" is written to the high impedance control register.

(2) A hazard may occur when the TOUT, FOUT, BZ or XBZ signal is turned ON and OFF.

(3) When fOSC3 is selected for the FOUT signal frequency, it is necessary to control the OSC3 oscillation circuit before output.

Refer to Section 4.3, "Oscillation Circuit", for the control and notes.

## 4.6 I/O Ports (P00–P03, P10–P13, P20–P23 and P30–P33)

### 4.6.1 Configuration of I/O ports

The E0C63567 has 16 bits general-purpose I/O ports. Figure 4.6.1.1 shows the configuration of the I/O port.

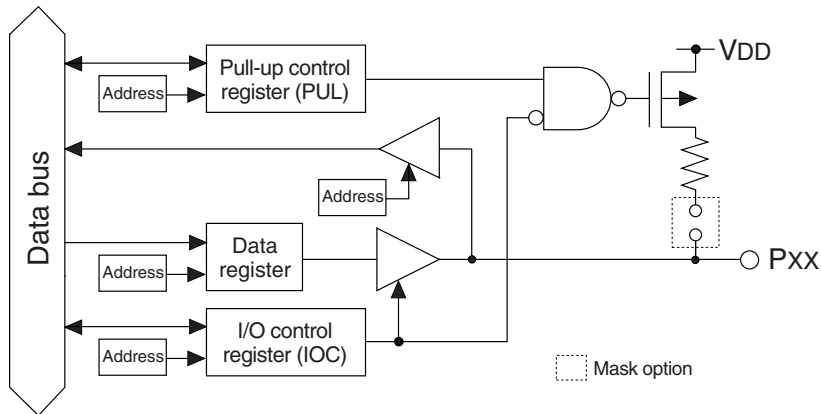

Fig. 4.6.1.1 Configuration of I/O port

The I/O port terminals P10 to P13 are shared with the serial interface input/output terminals. The P22 and P23 terminals are shared with the special output (CL, FR) terminals. The software can select the function to be used.

At initial reset, these are all set to the I/O port.

Table 4.6.1.1 shows the setting of the input/output terminals by function selection.

Table 4.6.1.1 Function setting of input/output terminals

Terminal name	Terminal status at initial reset	Special output		Serial I/F		
		CL	FR	Async.	Clk-sync. Master	Clk-sync. Slave
P00–P03	P00–P03 (Input & Pull-up *)	P00–P03	P00–P03	P00–P03	P00–P03	P00–P03

P20	P20 (Input & Pull-up *)	P20	P20	P20	P20	P20
P21	P21 (Input & Pull-up *)	P21	P21	P21	P21	P21
P22	P22 (Input & Pull-up *)	CL	P22	P22	P22	P22
P23	P23 (Input & Pull-up *)	P23	FR	P23	P23	P23
P30–P33	P30–P33 (Input & Pull-up *)	P30–P33	P30–P33	P30–P33	P30–P33	P30–P33

\* When "with pull-up resistor" is selected by the mask option (high impedance when "gate direct" is set)

When these ports are used as I/O ports, the ports can be set to either input mode or output mode individually (in 1-bit unit). Modes can be set by writing data to the I/O control registers.

Refer to Section 4.11, "Serial Interface", for control of the serial interface.

### 4.6.2 Mask option

In the I/O ports, the output specification during output mode can be selected from complementary output and N-channel open drain output by mask option. They are selected in 1-bit units.

When N-channel open drain output is selected, do not apply a voltage exceeding the power supply voltage to the port.

The mask option also allows selection of whether the pull-up resistor is used or not during input mode. They are selected in 1-bit units or 4-bit units depending on the terminal group.

Ports to be selected in 1-bit units: P20, P21, P22, P23

Ports to be selected in 4-bit units: P00–P03, P10–P13, P30–P33

When "without pull-up" during the input mode is selected, take care that the floating status does not occur.

This option is effective even when I/O ports are used for special output or input/output of the serial interface.

### 4.6.3 I/O control registers and input/output mode

Input or output mode can be set for the I/O ports by writing data into the corresponding I/O control registers IOCxx.

To set the input mode, write "0" to the I/O control register. When an I/O port is set to input mode, it becomes high impedance status and works as an input port.

However, when the pull-up explained in the following section has been set by software, the input line is pulled up only during this input mode.

To set the output mode, write "1" is to the I/O control register. When an I/O port is set to output mode, it works as an output port, it outputs a high level (VDD) when the port output data is "1", and a low level (VSS) when the port output data is "0".

If perform the read out in each mode; when output mode, the register value is read out, and when input mode, the port value is read out.

At initial reset, the I/O control registers are set to "0", and the I/O ports enter the input mode.

The I/O control registers of the ports that are set as special output or input/output for the serial interface can be used as general purpose registers that do not affect the I/O control. (See Table 4.6.1.1.)

### 4.6.4 Pull-up during input mode

A pull-up resistor that operates during the input mode is built into each I/O port of the E0C63567. Mask option can set the use or non-use of this pull-up.

The pull-up resistor becomes effective by writing "1" to the pull-up control register PULxx that corresponds to each port, and the input line is pulled up during the input mode. When "0" has been written, no pull-up is done.

At initial reset, the pull-up control registers are set to "1".

The pull-up control registers of the ports in which "without pull-up" have been selected can be used as general purpose registers.

Even when "with pull-up" has been selected, the pull-up control registers of the ports, that are set as special output or output for the serial interface, can be used as general purpose registers that do not affect the pull-up control. (See Table 4.6.1.1.)

The pull-up control registers of the port, that are set as input for the serial interface, function the same as the I/O port.

### 4.6.5 Special outputs (CL, FR)

The I/O ports P22 and P23 can be used as special output ports that output CL and FR signals by switching the function with software. Since P22 and P23 are set to I/O port (input mode) at initial reset, when using the special outputs, select the special output function using the EXLCDC register.

The data registers, I/O control registers and pull-up control registers of the ports set in the special output can be used as general purpose registers that do not affect the output.

When "1" is written to the EXLCDC register, P22 is set to the CL output port and P23 is set to the FR output port.

The CL and FR signals are LCD synchronous signal (CL) and LCD flame signal (FR) for externally expanded LCD driver, and are output from the P22 terminal and P23 terminal when the functions are switched by the EXLCDC register.

The following tables show the frequencies of the CL and FR signals.

Table 4.6.5.1 CL signal frequency

OSC1 oscillation frequency	When 1/8 duty is selected	When 1/16 duty is selected	When 1/17 duty is selected
32.768 kHz	512 Hz	1,024 Hz	1,024 Hz
60 kHz	937.5 Hz	1,875 Hz	1,875 Hz

Table 4.6.5.2 FR signal frequency

OSC1 oscillation frequency	When 1/8 duty is selected	When 1/16 duty is selected	When 1/17 duty is selected
32.768 kHz	32 Hz	32 Hz	30.12 Hz
60 kHz	58.6 Hz	58.6 Hz	55.2 Hz

Refer to Section 4.7, "LCD Driver", for control of the LCD drive duty.

*Note: A hazard may occur when the CL signal or FR signal is turned ON or OFF (when the port function is switched).*

Figure 4.6.5.1 shows the output waveforms of CL and FR signals.

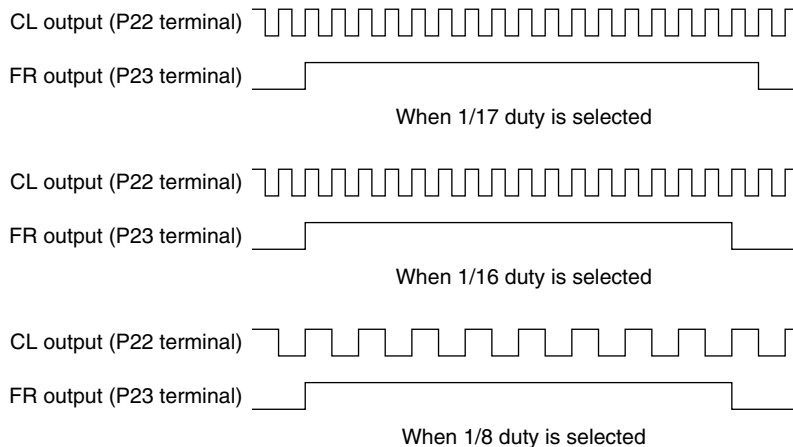

Fig. 4.6.5.1 Output waveforms of CL and FR signals

4.6.6 I/O memory of I/O ports

Tables 4.6.6.1(a) and (b) show the I/O addresses and the control bits for the I/O ports.

## (1) Selection of port function

### EXLCDC: Expanded LCD driver signal control register (FF61H•D3)

Sets P22 and P23 to the CL signal and the FR signal output ports.

When "1" is written: CL/FR signal output

When "0" is written: I/O port

Reading: Valid

When setting P22 to the CL (LCD synchronous signal) output and P23 to the FR (LCD frame signal) output, write "1" to this register and when they are used as I/O ports, write "0".

The CL and FR signals are output from the P22 terminal and P23 terminal immediately after the functions are switched by the EXLCDC register. In this case, the control registers for P22 and P23 can be used as general purpose registers that do not affect the output.

At initial reset, this register is set to "0".

### ESIF: Serial interface enable register (FF70H•D0)

Selects function for P10–P13.

When "1" is written: Serial interface input/output port

When "0" is written: I/O port

Reading: Valid

When using the serial interface, write "1" to this register and when P10–P13 are used as the I/O port, write "0". The terminal configuration within P10–P13 that are used for the serial interface is decided by the transfer mode (7-bit asynchronous, 8-bit asynchronous, clock synchronous slave, clock synchronous master) selected with the SMD1 and SMD0 registers.

In the clock synchronous slave mode, all the P10–P13 ports are set to the serial interface input/output port. In the clock synchronous master mode, P10–P12 are set to the serial interface input/output port and P13 can be used as the I/O port. In the 8/7-bit asynchronous mode, P10 and P11 are set to the serial interface input/output port and P12 and P13 can be used as the I/O port.

At initial reset, this register is set to "0".

**(2) I/O port control****P00–P03: P0 I/O port data register (FF42H)****P10–P13: P1 I/O port data register (FF46H)****P20–P23: P2 I/O port data register (FF4AH)****P30–P33: P3 I/O port data register (FF4EH)**

I/O port data can be read and output data can be set through these registers.

**•When writing data**

When "1" is written: High level

When "0" is written: Low level

When an I/O port is set to the output mode, the written data is output unchanged from the I/O port terminal. When "1" is written as the port data, the port terminal goes high (VDD), and when "0" is written, the terminal goes low (VSS).

Port data can be written also in the input mode.

**•When reading data**

When "1" is read: High level

When "0" is read: Low level

The terminal voltage level of the I/O port is read out. When the I/O port is in the input mode the voltage level being input to the port terminal can be read out; in the output mode the register value can be read. When the terminal voltage is high (VDD) the port data that can be read is "1", and when the terminal voltage is low (VSS) the data is "0".

When "with pull-up resistor" has been selected with the mask option and the PUL register is set to "1", the built-in pull-up resistor goes ON during input mode, so that the I/O port terminal is pulled up.

The data registers of the port, which are set for the special output (P22, P23) or input/output of the serial interface (P10–P12 or P10–P13), become general-purpose registers that do not affect the input/output.

*Note: When in the input mode, I/O ports are changed from low to high by pull-up resistor, the rise of the waveform is delayed on account of the time constant of the pull-up resistor and input gate capacitance. Hence, when fetching input ports, set an appropriate wait time.*

*Particular care needs to be taken of the key scan during key matrix configuration.*

*Make this waiting time the amount of time or more calculated by the following expression.*

$$10 \times C \times R$$

*C: terminal capacitance 5 pF + parasitic capacitance ? pF*

*R: pull-up resistance 330 kΩ*

**IOC00–IOC03: P0 port I/O control register (FF40H)****IOC10–IOC13: P1 port I/O control register (FF44H)****IOC20–IOC23: P2 port I/O control register (FF48H)****IOC30–IOC33: P3 port I/O control register (FF4CH)**

The input and output modes of the I/O ports are set with these registers.

When "1" is written: Output mode

When "0" is written: Input mode

Reading: Valid

The input and output modes of the I/O ports are set in 1-bit unit.

Writing "1" to the I/O control register makes the corresponding I/O port enter the output mode, and writing "0" induces the input mode.

At initial reset, these registers are all set to "0", so the I/O ports are in the input mode.

The I/O control registers of the port, which are set for the special output (P22, P23) or input/output of the serial interface (P10–P12 or P10–P13), become general-purpose registers that do not affect the input/output.

**PUL00–PUL03: P0 port pull-up control register (FF41H)**

**PUL10–PUL13: P1 port pull-up control register (FF45H)**

**PUL20–PUL23: P2 port pull-up control register (FF49H)**

**PUL30–PUL33: P3 port pull-up control register (FF4DH)**

The pull-up during the input mode are set with these registers.

When "1" is written: Pull-up ON

When "0" is written: Pull-up OFF

Reading: Valid

The built-in pull-up resistor which is turned ON during input mode is set to enable in 1-bit units. (The pull-up resistor is included into the ports selected by the mask option.)

By writing "1" to the pull-up control register, the corresponding I/O ports are pulled up (during input mode), while writing "0" turns the pull-up function OFF.

At initial reset, these registers are all set to "1", so the pull-up function is set to ON.

The pull-up control registers of the ports in which the pull-up resistor is not included become the general purpose register. The registers of the ports that are set as special output or output for the serial interface can also be used as general purpose registers that do not affect the pull-up control.

The pull-up control registers of the port that are set as input for the serial interface function the same as the I/O port.

#### **4.6.7 Programming notes**

- (1) When in the input mode, I/O ports are changed from low to high by pull-up resistor, the rise of the waveform is delayed on account of the time constant of the pull-up resistor and input gate capacitance. Hence, when fetching input ports, set an appropriate wait time.

Particular care needs to be taken of the key scan during key matrix configuration.

Make this waiting time the amount of time or more calculated by the following expression.

$$10 \times C \times R$$

C: terminal capacitance 5 pF + parasitic capacitance ? pF

R: pull-up resistance 330 kΩ

- (2) When special output (CL, FR) has been selected, a hazard may occur when the signal is turned ON or OFF.

## 4.7 LCD Driver (COM0–COM16, SEG0–SEG59)

### 4.7.1 Configuration of LCD driver

The E0C63567 has 17 common terminals (COM0–COM16) and 60 segment terminals (SEG0–SEG59), so that it can drive a dot matrix type LCD with a maximum of 1,020 (60 × 17) dots.

The driving method is 1/17 duty, 1/16 duty or 1/8 duty dynamic drive with four voltages (1/4 bias), VC1, VC23, VC4 and VC5.

LCD display ON/OFF can be controlled by the software.

### 4.7.2 Power supply for LCD driving

VC1, VC23, VC4 and VC5 are the LCD (1/4 bias) drive voltages generated by the LCD system voltage circuit. These four output voltages can only be supplied to the externally expanded LCD driver.

Turning the LCD system voltage circuit ON or OFF is controlled with the LPWR register. When LPWR is set to "1", the LCD system voltage circuit outputs the LCD drive voltages VC1, VC23, VC4 and VC5 to the LCD driver.

The LCD system voltage circuit generates VC23 with the voltage regulator incorporated in itself, and generates three other voltages by boosting or reducing the voltage VC23. Table 4.7.2.1 shows the VC1, VC23, VC4 and VC5 voltage values and boost/reduce status.

Table 4.7.2.1 LCD drive voltage when generated internally

LCD drive voltage	VDD = 2.2 V to 2.5 V	VDD = 2.5 V to 5.5 V
VC1 = 1/2 × VC23	1/2 × VC23	1/2 × VC23
VC23 = (standard)	(1.950 to 2.4 V) × (VDD-0.1)/2.4	1.950 to 2.4 V
VC4 = 3/2 × VC23	3/2 × VC23	3/2 × VC23
VC5 = 2 × VC23	2 × VC23	2 × VC23

Note: The LCD drive voltage can be adjusted by the software (see Section 4.7.5). Values in the table are typical values.

### 4.7.3 LCD display control (ON/OFF) and switching of duty

#### (1) Display ON/OFF control

The E0C63567 incorporates the ALON and ALOFF registers to blink display. When "1" is written to ALON, all the dots go ON, and when "1" is written to ALOFF, all the dots go OFF. At such a time, an ON waveform or an OFF waveform is output from SEG terminals. When "0" is written to these registers, normal display is performed. Furthermore, when "1" is written to both of the ALON and ALOFF, ALON (all ON) has priority over the ALOFF (all OFF).

#### (2) Switching of drive duty

In the E0C63567, the drive duty can be set to 1/17, 1/16 or 1/8 by the software. This setting is done using the LDUTY1 and LDUTY0 registers as shown in Table 4.7.3.1.

Table 4.7.3.1 LCD drive duty setting

LDUTY1	LDUTY0	Drive duty	Common terminal used	Maximum segment number
1	*	1/8	COM0–COM7	480 (60 × 8)
0	1	1/16	COM0–COM15	960 (60 × 16)
0	0	1/17	COM0–COM16	1,020 (60 × 17)

Table 4.7.3.2 shows the frame frequencies corresponding to the OSC1 oscillation frequency and drive duty.

Table 4.7.3.2 Frame frequency

OSC1 oscillation frequency	When 1/8 duty is selected	When 1/16 duty is selected	When 1/17 duty is selected
32.768 kHz	32 Hz	32 Hz	30.12 Hz
60 kHz	58.6 Hz	58.6 Hz	55.2 Hz

Figure 4.7.3.1 shows the dynamic drive waveform for 1/4 bias.

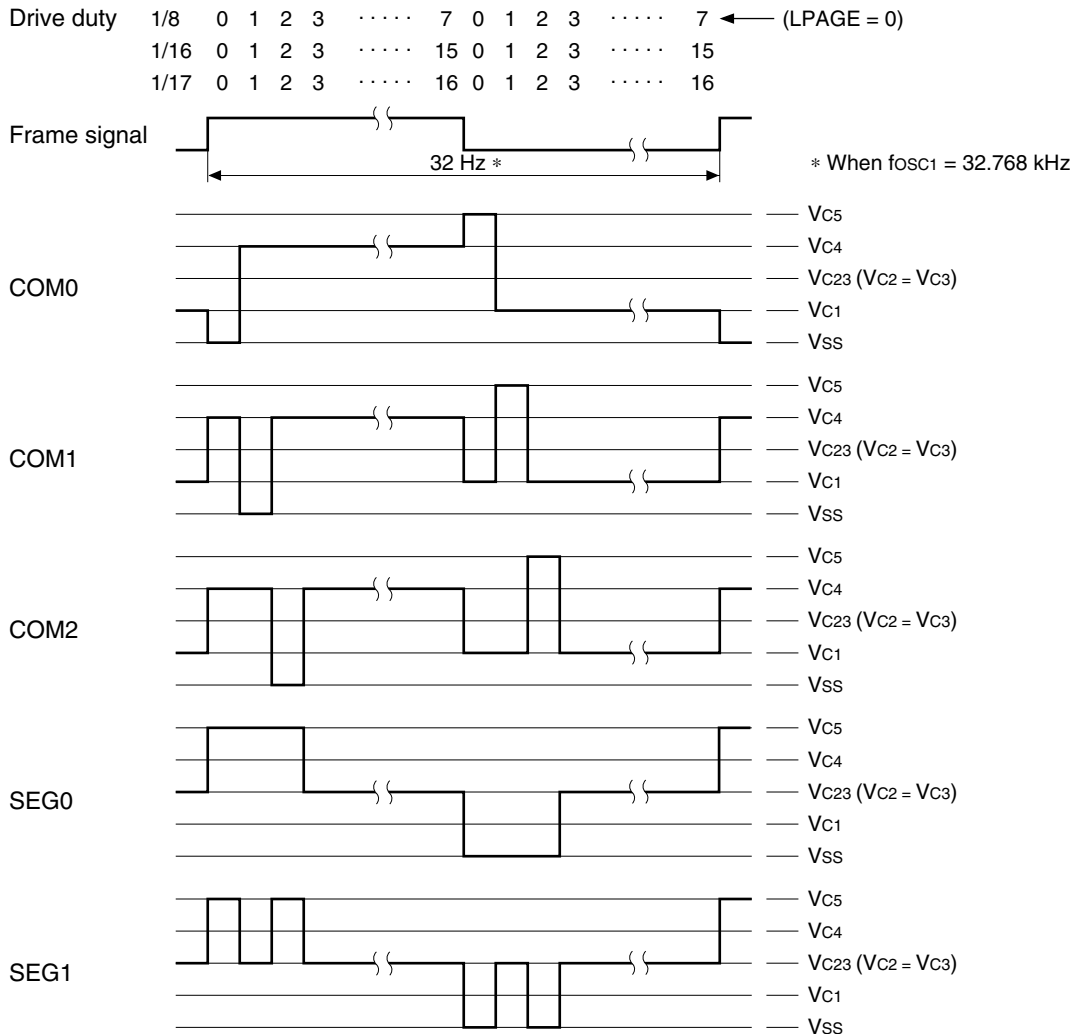

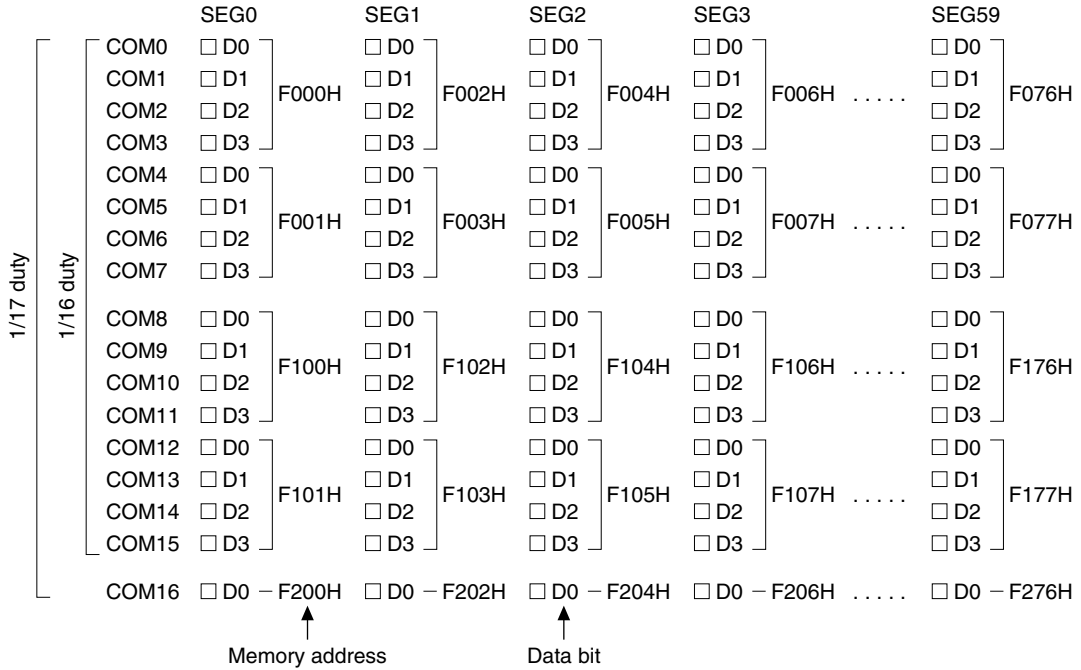

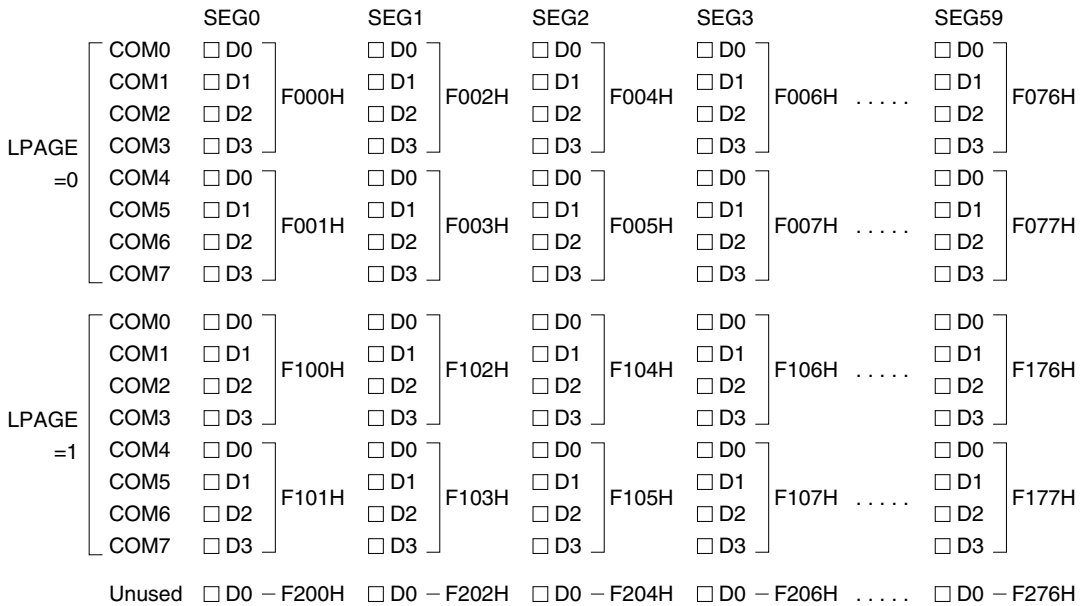

Fig. 4.7.3.1 Drive waveform for 1/4 bias

### 4.7.4 Display memory

The display memory is allocated to F000H–F276H in the data memory area and the addresses and the data bits correspond to COM and SEG outputs as shown in Figure 4.7.4.1.

(a) When 1/17 or 1/16 duty is selected

(b) When 1/8 duty is selected

Fig. 4.7.4.1 Correspondence between display memory and LCD dot matrix

When a bit in the display memory is set to "1", the corresponding LCD dot goes ON, and when it is set to "0", the dot goes OFF.

At 1/17 (1/16) duty drive, all data of COM0–COM16 (15) is output.

At 1/8 duty drive, data only corresponding to COM0–COM7 is output. However, since the display memory has capacity for two screens, it is designed so that the memory for COM8–COM15 shown in Figure 4.7.4.1 (a) can also be used as COM0–COM7. Select either F000H–F077H or F100H–F177H for the area to be displayed (to be output from COM0–COM7 terminals) using the LPAGE register. It can switch the screen in an instant.

At initial reset, the data memory content becomes undefined hence, there is need to initialize using the software.

The display memory has read/write capability, and the addresses that have not been used for LCD display can be used as general purpose registers.

*Note: When a program that access no memory mounted area (F078H–F0FFH, F178H–F1FFH, F201H, F203H, . . . , F277H) is made, the operation is not guaranteed.*

### 4.7.5 LCD contrast adjustment

In the E0C63567, the LCD contrast can be adjusted by the software.

It is realized by controlling the voltages VC1, VC23, VC4 and VC5 output from the LCD system voltage circuit. When these voltages are supplied to the externally expanded LCD driver, the expanded LCD contrast is adjusted at the same time.

The contrast can be adjusted to 16 levels as shown in Table 4.7.5.1.

Table 4.7.5.1 LCD contrast

No.	LC3	LC2	LC1	LC0	Contrast
0	0	0	0	0	light
1	0	0	0	1	↑
2	0	0	1	0	
3	0	0	1	1	
4	0	1	0	0	
5	0	1	0	1	
6	0	1	1	0	
7	0	1	1	1	
8	1	0	0	0	
9	1	0	0	1	
10	1	0	1	0	
11	1	0	1	1	
12	1	1	0	0	
13	1	1	0	1	
14	1	1	1	0	↓
15	1	1	1	1	dark

Setting the LC3–LC0 register affects the VC23 voltage, and other voltages change according to the VC23. As a result, the LCD contrast is adjusted.

The supply voltage VDD within the range from 2.2 to 2.5 V affects the VC23 voltage. Ordinarily, VC23 is 2.4 V (when VDD = 2.5 to 5.5 V) in the highest-contrast setting (No. 15 in Table 4.7.5.1), note, however, that VC23 will be VDD - 0.1 V when VDD = 2.2 to 2.5 V.

At room temperature, use setting number 7 or 8 as standard.

Since the contents of LC0–LC3 are undefined at initial reset, initialize it by the software.

### 4.7.6 I/O memory of LCD driver

Table 4.7.6.1 shows the I/O addresses and the control bits for the LCD driver. Figure 4.7.6.1 shows the display memory map.

Table 4.7.6.1 LCD driver control bits

Address	Register								Comment
	D3	D2	D1	D0	Name	Init *1	1	0	
FF60H	LDUTY1	LDUTY0	Dummy	LPWR	LDUTY1	0			LCD drive duty switch General-purpose register LCD power On/Off
					LDUTY0	0			
	R/W				Dummy	0			
					LPWR	0	On	Off	
FF61H	EXLDCDC	ALOFF	ALON	LPAGE	EXLDCDC	0	Enable	Disable	Expanded LCD driver signal control LCD all Off control LCD all On control Display memory area selection (when 1/8 duty is selected) General-purpose register when 1/16, 1/17 duty is selected
					ALOFF	1	All Off	Normal	
	R/W				ALON	0	All On	Normal	
					LPAGE	0	F100-F177	F000-F077	
FF62H	LC3	LC2	LC1	LC0	LC3	- *2			LCD contrast adjustment Contrast Light - Dark
					LC2	- *2			
	R/W				LC1	- *2			
					LC0	- *2			

- \*1 Initial value at initial reset
- \*2 Not set in the circuit
- \*3 Constantly "0" when being read

Fig. 4.7.6.1 Display memory map

#### LPWR: LCD power control (ON/OFF) register (FF60H•D0)

Turns the LCD system voltage circuit ON and OFF.

- When "1" is written: ON
- When "0" is written: OFF
- Reading: Valid

When "1" is written to the LPWR register, the LCD system voltage circuit goes ON and generates the LCD drive voltage. When "0" is written, all the LCD drive voltages go to VSS level.

It takes about 100 msec for the LCD drive voltage to stabilize after starting up the LCD system voltage circuit by writing "1" to the LPWR register.

At initial reset, this register is set to "0".

**LDUTY0, LDUTY1: LCD drive duty switching register (FF60H•D2, D3)**

Selects the LCD drive duty.

Table 4.7.6.2 Drive duty setting

LDUTY1	LDUTY0	Drive duty	Common terminal used	Maximum segment number
1	*	1/8	COM0–COM7	480 (60 × 8)
0	1	1/16	COM0–COM15	960 (60 × 16)
0	0	1/17	COM0–COM16	1,020 (60 × 17)

At initial reset, this register is set to "0".

**ALON: LCD all ON control register (FF61H•D1)**

Displays the all LCD dots ON.

When "1" is written: All LCD dots displayed

When "0" is written: Normal display

Reading: Valid

By writing "1" to the ALON register, all the LCD dots goes ON, and when "0" is written, it returns to normal display.

This function outputs an ON waveform to the SEG terminals, and does not affect the content of the display memory.

ALON has priority over ALOFF.

At initial reset, this register is set to "0".

**ALOFF: LCD all OFF control register (FF61H•D2)**

Fade outs the all LCD dots.

When "1" is written: All LCD dots fade out

When "0" is written: Normal display

Reading: Valid

By writing "1" to the ALOFF register, all the LCD dots goes OFF, and when "0" is written, it returns to normal display.

This function outputs an OFF waveform to the SEG terminals, and does not affect the content of the display memory.

At initial reset, this register is set to "1".

**LPAGE: LCD display memory selection register (FF61H•D0)**

Selects the display memory area at 1/8 duty drive.

When "1" is written: F100H–F177H

When "0" is written: F000H–F077H

Reading: Valid

By writing "1" to the LPAGE register, the data set in F100H–F177H (the second half of the display memory) is displayed, and when "0" is written, the data set in F000H–F077H (the first half of the display memory) is displayed.

This function is valid only when 1/8 duty is selected, and when 1/16 or 1/17 duty is selected, this register can be used as a general purpose register.

At initial reset, this register is set to "0".

**LC3–LC0: LCD contrast adjustment register (FF62H)**

Adjusts the LCD contrast.

LC3–LC0 = 0000B light

: :

LC3–LC0 = 1111B dark

At room temperature, use setting number 7 or 8 as standard.

At initial reset, LC3–LC0 are undefined.

### ***4.7.7 Programming notes***

- (1) When a program that access no memory mounted area (F078H–F0FFH, F178H–F1FFH, F201H, F203H, . . . , F277H) is made, the operation is not guaranteed.
- (2) Because at initial reset, the contents of display memory and LC3–LC0 (LCD contrast) are undefined, there is need to initialize by the software. Furthermore, take care of the registers LPWR and ALOFF because these are set so that the display goes OFF.

## 4.8 Clock Timer

### 4.8.1 Configuration of clock timer

The E0C63567 has a built-in clock timer that uses OSC1 (crystal oscillator) as the source oscillator. The clock timer is configured of an 8-bit binary counter that serves as the input clock, fOSC1 divided clock output from the prescaler. Timer data (128–16 Hz and 8–1 Hz) can be read out by the software.

Figure 4.8.1.1 is the block diagram for the clock timer.

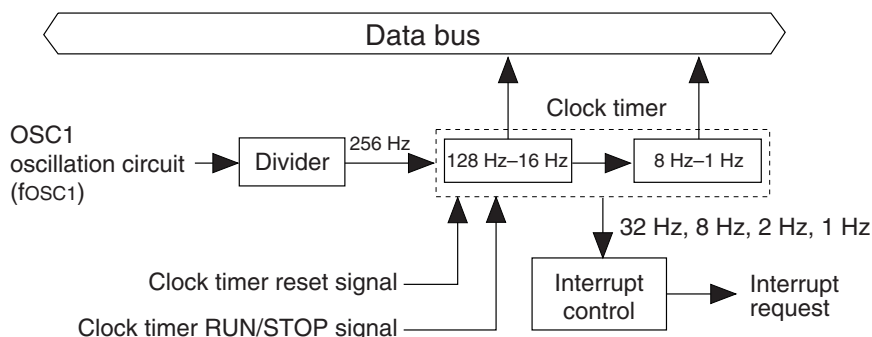

Fig. 4.8.1.1 Block diagram for the clock timer

Ordinarily, this clock timer is used for all types of timing functions such as clocks.

*Note:* When the CR oscillation circuit is selected as the OSC1 oscillation circuit by mask option, the frequencies and times differ from the values described in this section because the oscillation frequency will be 60 kHz (Typ.). Therefore, the clock timer can not be used for the clock function.

### 4.8.2 Data reading and hold function

The 8 bits timer data are allocated to the address FF79H and FF7AH.

<FF79H>	D0: TM0 = 128 Hz	D1: TM1 = 64 Hz	D2: TM2 = 32 Hz	D3: TM3 = 16 Hz
<FF7AH>	D0: TM4 = 8 Hz	D1: TM5 = 4 Hz	D2: TM6 = 2 Hz	D3: TM7 = 1 Hz

Since the clock timer data has been allocated to two addresses, a carry is generated from the low-order data within the count (TM0–TM3: 128–16 Hz) to the high-order data (TM4–TM7: 8–1 Hz). When this carry is generated between the reading of the low-order data and the high-order data, a content combining the two does not become the correct value (the low-order data is read as FFH and the high-order data becomes the value that is counted up 1 from that point).

The high-order data hold function in the E0C63567 is designed to operate to avoid this. This function temporarily stops the counting up of the high-order data (by carry from the low-order data) at the point where the low-order data has been read and consequently the time during which the high-order data is held is the shorter of the two indicated here following.

1. Period until it reads the high-order data.
2. 0.48–1.5 msec (Varies due to the read timing.)

*Note:* Since the low-order data is not held when the high-order data has previously been read, the low-order data should be read first.

### 4.8.3 Interrupt function

The clock timer can cause interrupts at the falling edge of 32 Hz, 8 Hz, 2 Hz and 1 Hz signals. Software can set whether to mask any of these frequencies.

Figure 4.8.3.1 is the timing chart of the clock timer.

Fig. 4.8.3.1 Timing chart of clock timer

As shown in Figure 4.8.3.1, interrupt is generated at the falling edge of the frequencies (32 Hz, 8 Hz, 2 Hz, 1 Hz). At this time, the corresponding interrupt factor flag (IT0, IT1, IT2, IT3) is set to "1". Selection of whether to mask the separate interrupts can be made with the interrupt mask registers (EIT0, EIT1, EIT2, EIT3). However, regardless of the interrupt mask register setting, the interrupt factor flag is set to "1" at the falling edge of the corresponding signal.

### 4.8.4 I/O memory of clock timer

Table 4.8.4.1 shows the I/O addresses and the control bits for the clock timer.

Table 4.8.4.1 Control bits of clock timer

Address	Register				Name	Init *1	1	0	Comment
	D3	D2	D1	D0					
FF78H	0	0	TMRST	TMRUN	0 *3	- *2			Unused
	R		W	R/W	0 *3	- *2			Unused
	R		W	R/W	TMRST*3	Reset	Reset	Invalid	Clock timer reset (writing)
FF79H	TM3	TM2	TM1	TM0	TMRUN	0	Run	Stop	Clock timer Run/Stop
	R				TM3	0			Clock timer data (16 Hz)
	R				TM2	0			Clock timer data (32 Hz)
	R				TM1	0			Clock timer data (64 Hz)
FF7AH	TM7	TM6	TM5	TM4	TM0	0			Clock timer data (128 Hz)
	R				TM7	0			Clock timer data (1 Hz)
	R				TM6	0			Clock timer data (2 Hz)
	R				TM5	0			Clock timer data (4 Hz)
FFE6H	EIT3	EIT2	EIT1	EIT0	TM4	0			Clock timer data (8 Hz)
	R/W				EIT3	0	Enable	Mask	Interrupt mask register (Clock timer 1 Hz)
	R/W				EIT2	0	Enable	Mask	Interrupt mask register (Clock timer 2 Hz)
	R/W				EIT1	0	Enable	Mask	Interrupt mask register (Clock timer 8 Hz)
FFF6H	IT3	IT2	IT1	IT0	EIT0	0	Enable	Mask	Interrupt mask register (Clock timer 32 Hz)
	R/W				IT3	0	(R)	(R)	Interrupt factor flag (Clock timer 1 Hz)
	R/W				IT2	0	Yes	No	Interrupt factor flag (Clock timer 2 Hz)
	R/W				IT1	0	(W)	(W)	Interrupt factor flag (Clock timer 8 Hz)
R/W				IT0	0	Reset	Invalid	Interrupt factor flag (Clock timer 32 Hz)	

\*1 Initial value at initial reset

\*2 Not set in the circuit

\*3 Constantly "0" when being read

#### TM0–TM7: Timer data (FF79H, FF7AH)

The 128–1 Hz timer data of the clock timer can be read out with these registers. These eight bits are read only, and writing operations are invalid.

By reading the low-order data (FF79H), the high-order data (FF7AH) is held until reading or for 0.48–1.5 msec (one of shorter of them).

At initial reset, the timer data is initialized to "00H".

#### TMRST: Clock timer reset (FF78H•D1)

This bit resets the clock timer.

When "1" is written: Clock timer reset

When "0" is written: No operation

Reading: Always "0"

The clock timer is reset by writing "1" to TMRST. When the clock timer is reset in the RUN status, operation restarts immediately. Also, in the STOP status the reset data is maintained. No operation results when "0" is written to TMRST.

This bit is write-only, and so is always "0" at reading.

#### TMRUN: Clock timer RUN/STOP control register (FF78H•D0)

Controls RUN/STOP of the clock timer.

When "1" is written: RUN

When "0" is written: STOP

Reading: Valid

The clock timer enters the RUN status when "1" is written to the TMRUN register, and the STOP status when "0" is written. In the STOP status, the timer data is maintained until the next RUN status or the timer is reset. Also, when the STOP status changes to the RUN status, the data that is maintained can be used for resuming the count.

At initial reset, this register is set to "0".

**EIT0: 32 Hz interrupt mask register (FFE6H•D0)**

**EIT1: 8 Hz interrupt mask register (FFE6H•D1)**

**EIT2: 2 Hz interrupt mask register (FFE6H•D2)**

**EIT3: 1 Hz interrupt mask register (FFE6H•D3)**

These registers are used to select whether to mask the clock timer interrupt.

When "1" is written: Enabled

When "0" is written: Masked

Reading: Valid

The interrupt mask registers (EIT0, EIT1, EIT2, EIT3) are used to select whether to mask the interrupt to the separate frequencies (32 Hz, 8 Hz, 2 Hz, 1 Hz).

At initial reset, these registers are set to "0".

**IT0: 32 Hz interrupt factor flag (FFF6H•D0)**

**IT1: 8 Hz interrupt factor flag (FFF6H•D1)**

**IT2: 2 Hz interrupt factor flag (FFF6H•D2)**

**IT3: 1 Hz interrupt factor flag (FFF6H•D3)**

These flags indicate the status of the clock timer interrupt.

When "1" is read: Interrupt has occurred

When "0" is read: Interrupt has not occurred

When "1" is written: Flag is reset

When "0" is written: Invalid

The interrupt factor flags (IT0, IT1, IT2, IT3) correspond to the clock timer interrupts of the respective frequencies (32 Hz, 8 Hz, 2 Hz, 1 Hz). The software can judge from these flags whether there is a clock timer interrupt. However, even if the interrupt is masked, the flags are set to "1" at the falling edge of the signal.

These flags are reset to "0" by writing "1" to them.

After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.

At initial reset, these flags are set to "0".

#### **4.8.5 Programming notes**

- (1) Be sure to read timer data in the order of low-order data (TM0–TM3) then high-order data (TM4–TM7).
- (2) After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.
- (3) When the CR oscillation circuit is selected as the OSC1 oscillation circuit by mask option, the frequencies and times differ from the values described in this section because the oscillation frequency will be 60 kHz (Typ.). Therefore, the clock timer can not be used for the clock function.

## 4.9 Stopwatch Timer

### 4.9.1 Configuration of stopwatch timer

The E0C63567 has 1/100 sec unit and 1/10 sec unit stopwatch timer built-in. The stopwatch timer is configured with a 2 levels 4-bit BCD counter which has an input clock approximating 100 Hz signal (signal divided from OSC1 to the closest 100 Hz) and data can be read in units of 4 bits by software. Figure 4.9.1.1 shows the configuration of the stopwatch timer.

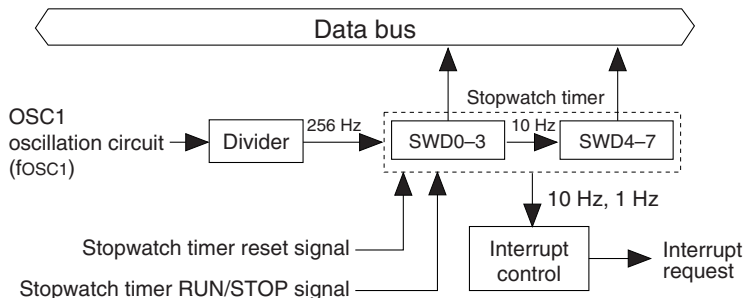

Fig. 4.9.1.1 Configuration of stopwatch timer

The stopwatch timer can be used as a separate timer from the clock timer. In particular, digital watch stopwatch functions can be realized easily with software.

*Note:* When the CR oscillation circuit is selected as the OSC1 oscillation circuit by mask option, the frequencies and times differ from the values described in this section because the oscillation frequency will be 60 kHz (Typ.). Therefore, this timer can not be used for the stopwatch function.

### 4.9.2 Count-up pattern

The stopwatch timer is configured of 4-bit BCD counters SWD0–SWD3 and SWD4–SWD7. The counter SWD0–SWD3, at the stage preceding the stopwatch timer, has an approximated 100 Hz signal for the input clock. It counts up every 1/100 sec, and generates an approximated 10 Hz signal. The counter SWD4–SWD7 has an approximated 10 Hz signal generated by the counter SWD0–SWD3 for the input clock. In count-up every 1/10 sec, and generated 1 Hz signal.

Figure 4.9.2.1 shows the count-up pattern of the stopwatch timer.

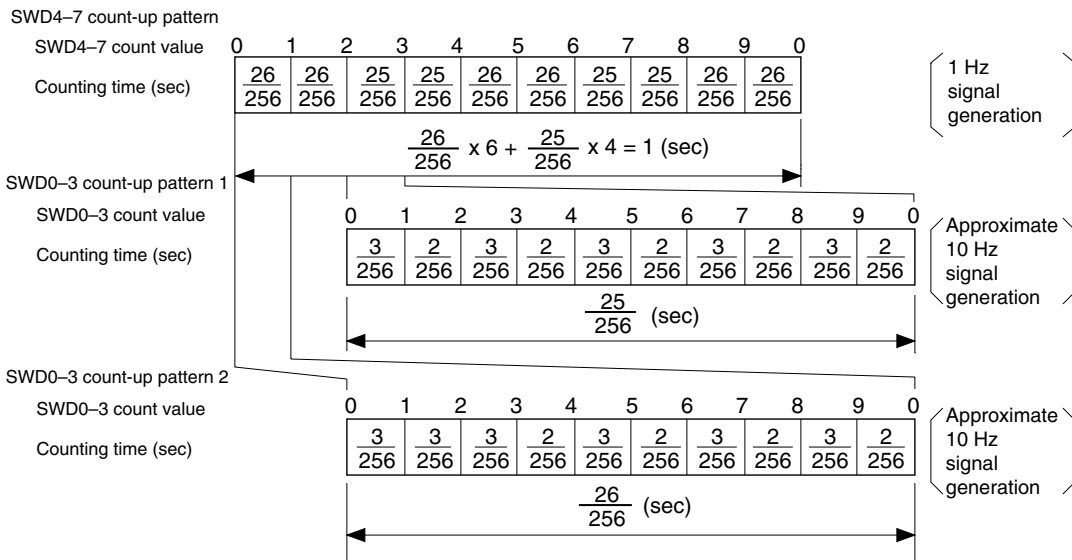

Fig. 4.9.2.1 Count-up pattern of stopwatch timer

SWD0–SWD3 generates an approximated 10 Hz signal from the basic 256 Hz signal ( $f_{OSC1}$  dividing clock). The count-up intervals are  $2/256$  sec and  $3/256$  sec, so that finally two patterns are generated:  $25/256$  sec and  $26/256$  sec intervals. Consequently, these patterns do not amount to an accurate  $1/100$  sec. SWD4–SWD7 counts the approximated 10 Hz signals generated by the  $25/256$  sec and  $26/256$  sec intervals in the ratio of 4 : 6, to generate a 1 Hz signal. The count-up intervals are  $25/256$  sec and  $26/256$  sec, which do not amount to an accurate  $1/10$  sec.

### 4.9.3 Interrupt function

The stopwatch timers SWD0–SWD3 and SWD4–SWD7, through their respective overflows, can generate 10 Hz (approximate 10 Hz) and 1 Hz interrupts.

Figure 4.9.3.1 shows the timing chart for the stopwatch timer.

Fig. 4.9.3.1 Timing chart for stopwatch timer

The stopwatch interrupts are generated by the overflow of their respective counters SWD0–SWD3 and SWD4–SWD7 (changing "9" to "0"). At this time, the corresponding interrupt factor flags (ISW10 and ISW1) are set to "1".

The respective interrupts can be masked separately using the interrupt mask registers (EISW10 and EISW1). However, regardless of the setting of the interrupt mask registers, the interrupt factor flags are set to "1" by the overflow of their corresponding counters.

### 4.9.4 I/O memory of stopwatch timer

Table 4.9.4.1 shows the I/O addresses and the control bits for the stopwatch timer.

Table 4.9.4.1 Control bits of stopwatch timer

Address	Register								Comment	
	D3	D2	D1	D0	Name	Init *1	1	0		
FF7CH	0	0	SWRST	SWRUN	0 *3	- *2			Unused	
					0 *3	- *2			Unused	
	R		W	R/W	SWRST*3	Reset	Reset	Invalid	Stopwatch timer reset (writing)	
FF7DH	SWD3		SWD2	SWD1	SWD0	0			Stopwatch timer data BCD (1/100 sec)	
	R				SWRUN	0	Run	Stop		
	SWD7		SWD6	SWD5	SWD4	0				Stopwatch timer data BCD (1/10 sec)
	R				SWD7	0				
FF7EH	SWD3		SWD2	SWD1	SWD0	0			Stopwatch timer data BCD (1/100 sec)	
	R				SWD7	0				
	SWD7		SWD6	SWD5	SWD4	0				
FFE7H	0	0	EISW1	EISW10	0 *3	- *2			Unused	
					0 *3	- *2			Unused	
	R		R/W		EISW1	0	Enable	Mask	Interrupt mask register (Stopwatch timer 1 Hz)	
FFF7H	0	0	ISW1	ISW10	0 *3	- *2	(R)	(R)	Unused	
					0 *3	- *2	Yes	No	Unused	
	R		R/W		ISW1	0	(W)	(W)	Interrupt factor flag (Stopwatch timer 1 Hz)	
FFF7H	R		R/W		ISW10	0	Reset	Invalid	Interrupt factor flag (Stopwatch timer 10 Hz)	

\*1 Initial value at initial reset

\*2 Not set in the circuit

\*3 Constantly "0" when being read

#### SWD0–SWD7: Stopwatch timer data (FF7DH, FF7EH)

The 1/100 sec and the 1/10 sec data (BCD) can be read from SWD0–SWD3 and SWD4–SWD7, respectively. These eight bits are read only, and writing operations are invalid.

At initial reset, the timer data is initialized to "00H".

#### SWRST: Stopwatch timer reset (FF7CH•D1)

When "1" is written: Stopwatch timer reset

When "0" is written: No operation

Reading: Always "0"

The stopwatch timer is reset by writing "1" to SWRST. All timer data is set to "0". When the stopwatch timer is reset in the RUN status, operation restarts immediately. Also, in the STOP status the reset data is maintained. No operation results when "0" is written to SWRST.

This bit is write-only, and so is always "0" at reading.

#### SWRUN: Stopwatch timer RUN/STOP control register (FF7CH•D0)

Controls RUN/STOP of the stopwatch timer.

When "1" is written: RUN

When "0" is written: STOP

Reading: Valid

The stopwatch timer enters the RUN status when "1" is written to the SWRUN register, and the STOP status when "0" is written.

In the STOP status, the timer data is maintained until the next RUN status or the timer is reset. Also, when the STOP status changes to the RUN status, the data that is maintained can be used for resuming the count.

When data of the counter is read at run mode, proper reading may not be obtained due to the carry from low-order digits (SWD0–SWD3) into high-order digits (SWD4–SWD7) (i.e., in case SWD0–SWD3 and SWD4–SWD7 reading span the timing of the carry). To avoid this occurrence, perform the reading after suspending the counter once and then set the SWRUN to "1" again.

Moreover, it is required that the suspension period not exceed 976  $\mu$ sec (1/4 cycle of 256 Hz).

At initial reset, this register is set to "0".

**EISW10: 10Hz interrupt mask register (FFE7H•D0)****EISW1: 1Hz interrupt mask register (FFE7H•D1)**

These registers are used to select whether to mask the stopwatch timer interrupt.

When "1" is written: Enabled

When "0" is written: Masked

Reading: Valid

The interrupt mask registers (EISW10, EISW1) are used to select whether to mask the interrupt to the separate frequencies (10 Hz, 1 Hz).

At initial reset, these registers are set to "0".

**ISW10: 10 Hz interrupt factor flag (FFF7H•D0)****ISW1: 1 Hz interrupt factor flag (FFF7H•D1)**

These flags indicate the status of the stopwatch timer interrupt.

When "1" is read: Interrupt has occurred

When "0" is read: Interrupt has not occurred

When "1" is written: Flag is reset

When "0" is written: Invalid

The interrupt factor flags ISW10 and ISW1 correspond to 10 Hz and 1 Hz stopwatch timer interrupts, respectively. The software can judge from these flags whether there is a stopwatch timer interrupt.

However, even if the interrupt is masked, the flags are set to "1" by the overflow of the corresponding counters.

These flags are reset to "0" by writing "1" to them.

After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.

At initial reset, these flags are set to "0".

### ***4.9.5 Programming notes***

- (1) When data of the counter is read at run mode, perform the reading after suspending the counter once and then set SWRUN to "1" again. Moreover, it is required that the suspension period not exceed 976  $\mu$ sec (1/4 cycle of 256 Hz).
- (2) After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.
- (3) When the CR oscillation circuit is selected as the OSC1 oscillation circuit by mask option, the frequencies and times differ from the values described in this section because the oscillation frequency will be 60 kHz (Typ.). Therefore, this timer can not be used for the stopwatch function.

## 4.10 Programmable Timer

### 4.10.1 Configuration of programmable timer

The E0C63567 has two 8-bit programmable timer systems (timer 0 and timer 1) built-in. Timer 0 and timer 1 are composed of 8-bit presetable down counters and they can be used as 8-bit × 2 channel programmable timers. Timer 0 also has an event counter function using the K13 input port terminal.

Figure 4.10.1.1 shows the configuration of the programmable timer.

The programmable timer is designed to count down from the initial value set in the counter with software. An underflow according to the initial value occurs by counting down and is used for the following functions:

- Presetting the initial value to the counter to generate the periodical underflow signal
- Generating an interrupt
- Generating a TOUT signal output from the R02 output port terminal
- Generating the synchronous clock source for the serial interface (timer 1 underflow is used, and it is possible to set the transfer rate)

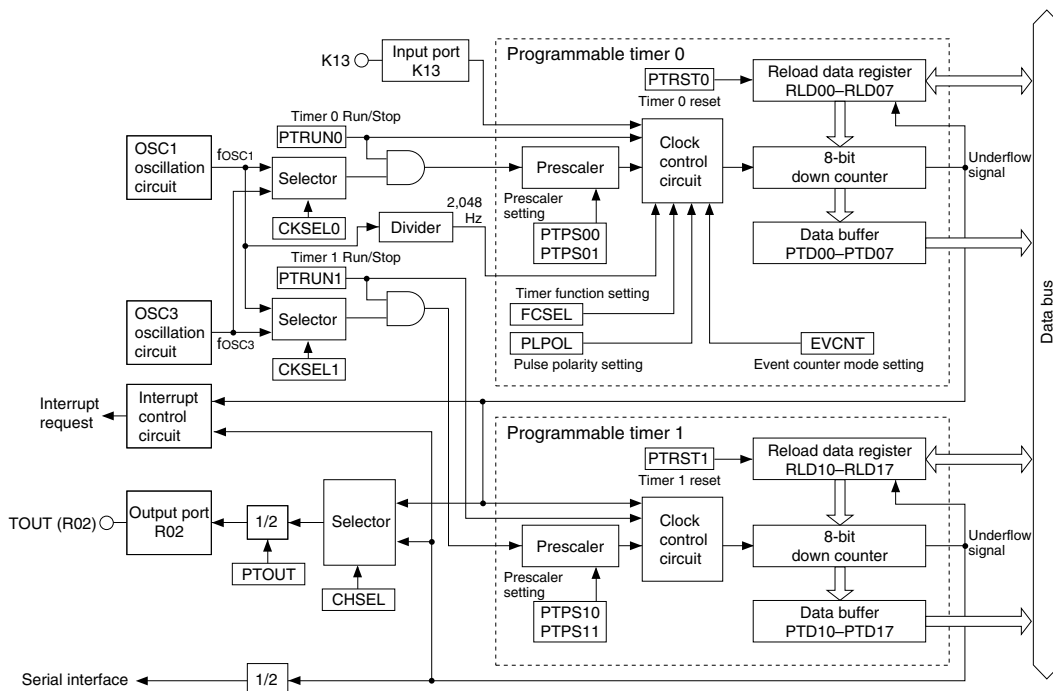

Fig. 4.10.1.1 Configuration of programmable timer

### 4.10.2 Setting of initial value and counting down

Timers 0 and 1 each have a down counter and reload data register.

The reload data registers RLD00–RLD07 (timer 0) and RLD10–RLD17 (timer 1) are used to set the initial value to the down counter.

By writing "1" to the timer reset bit PTRST0 (timer 0) or PTRST1 (timer 1), the down counter loads the initial value set in the reload register RLD. Therefore, down-counting is executed from the stored initial value by the input clock.

The registers PTRUN0 (timer 0) and PTRUN1 (timer 1) are provided to control the RUN/STOP for timers 0 and 1. By writing "1" to the register after presetting the reload data to the down counter, the down counter starts counting down. Writing "0" stops the input count clock and the down counter stops counting. This control (RUN/STOP) does not affect the counter data. The counter maintains its data while stopped, and can restart counting continuing from that data.

The counter data can be read via the data buffers PTD00–PTD07 (timer 0) and PTD10–PTD17 (timer 1) in optional timing. However, the counter has the data hold function the same as the clock timer, that holds the high-order data when the low-order data is read in order to prevent the borrowing operation between low- and high-order reading, therefore be sure to read the low-order data first.

The counter reloads the initial value set in the reload data register RLD when an underflow occurs through the count down. It continues counting down from the initial value after reloading.

In addition to reloading the counter, this underflow signal controls the interrupt generation, pulse (TOUT signal) output and clock supplying to the serial interface.

Fig. 4.10.2.1 Basic operation timing of down counter

### 4.10.3 Counter mode

The programmable timer can operate in two counter modes, timer mode and event counter mode. It can be selected by software.

#### (1) Timer mode

The timer mode counts down using the prescaler output as an input clock. In this mode, the programmable timer operates as a periodical timer using the OSC1 or OSC3 oscillation clock as a clock source. Timer 0 can operate in both the timer mode and the event counter mode. The mode can be switched using the timer 0 counter mode selection register EVCNT. When the EVCNT register is set to "0", timer 0 operates in the timer mode.

Timer 1 operates only in the timer mode.

At initial reset, this mode is set.

Refer to Section 4.10.2, "Setting of initial value and counting down" for basic operation and control.

The input clock in the timer mode is generated by the prescaler built into the programmable timer. The prescaler generates the input clock by dividing the OSC1 or OSC3 oscillation clock. Refer to the next section for setting the input clock.

#### (2) Event counter mode

The timer 0 has an event counter function that counts an external clock input to the input port K13. This function is selected by writing "1" to the timer 0 counter mode selection register EVCNT. The timer 1 operates only in the timer mode, and cannot be used as an event counter.

In the event counter mode, the clock is supplied to timer 0 from outside of the IC, therefore, the settings of the timer 0 prescaler division ratio selection registers PTPS00 and PTPS01 and the settings of the timer 0 source clock selection register CKSEL0 become invalid.

Count down timing can be selected from either the falling or rising edge of the input clock using the timer 0 pulse polarity selection register PLPOL. When "0" is written to the PLPOL register, the falling edge is selected, and when "1" is written, the rising edge is selected. The count down timing is shown in Figure 4.10.3.1.

Fig. 4.10.3.1 Timing chart in event counter mode

The event counter mode also includes a noise reject function to eliminate noise such as chattering on the external clock (K13 input signal). This function is selected by writing "1" to the timer 0 function selection register FCSSEL.

When "with noise rejector" is selected, an input pulse width for both low and high levels must be 0.98 msec\* or more to count reliably. The noise rejector allows the counter to input the clock at the second falling edge of the internal 2,048 Hz\* signal after changing the input level of the K13 input port terminal. Consequently, the pulse width of noise that can reliably be rejected is 0.48 msec\* or less. (\*:  $f_{OSC1} = 32.768 \text{ kHz}$ ).

Figure 4.10.3.2 shows the count down timing with noise rejecter.

Fig. 4.10.3.2 Count down timing with noise rejecter

The operation of the event counter mode is the same as the timer mode except it uses the K13 input as the clock.

Refer to Section 4.10.2, "Setting of initial value and counting down" for basic operation and control.

#### 4.10.4 Setting of input clock in timer mode

Timer 0 and timer 1 each include a prescaler. The prescalers generate the input clock for each timer by dividing the source clock supplied from the OSC1 or OSC3 oscillation circuit. The source clock (OSC1 or OSC3) and the division ratio of the prescaler can be selected with software for timer 0 and timer 1 individually.

The set input clock is used for the count clock during operation in the timer mode. When the timer 0 is used in the event counter mode, the following settings become invalid.

The input clock is set in the following sequence.

##### (1) Selection of source clock

Select the source clock input to each prescaler from either OSC1 or OSC3. This selection is done using the source clock selection registers CKSEL0 (timer 0) and CKSEL1 (timer 1); when "0" is written to the register, OSC1 is selected and when "1" is written, OSC3 is selected.

When the OSC3 oscillation clock is selected for the clock source, it is necessary to turn the OSC3 oscillation ON, prior to using the programmable timer. However the OSC3 oscillation circuit requires a time at least 5 msec from turning the circuit ON until the oscillation stabilizes. Therefore, allow an adequate interval from turning the OSC3 oscillation circuit ON to starting the programmable timer. Refer to Section 4.3, "Oscillation Circuit", for the control and notes of the OSC3 oscillation circuit. At initial reset, the OSC3 oscillation circuit is set in the OFF state.

##### (2) Selection of prescaler division ratio

Select the division ratio for each prescaler from among 4 types. This selection is done using the prescaler division ratio selection registers PTPS00/PTPSC01 (timer 0) and PTPS10/PTPS11 (timer 1). Table 4.10.4.1 shows the correspondence between the setting value and the division ratio.

Table 4.10.4.1 Selection of prescaler division ratio

PTPS11 PTPS01	PTPS10 PTPS00	Prescaler division ratio
1	1	Source clock / 256
1	0	Source clock / 32
0	1	Source clock / 4
0	0	Source clock / 1

By writing "1" to the register PTRUN0 (timer 0) or PTRUN1 (timer 1), the prescaler inputs the source clock and outputs the clock divided by the selected division ratio. The counter starts counting down by inputting the clock.

### 4.10.5 Interrupt function

The programmable timer can generate an interrupt due to an underflow of the timer 0 and timer 1. See Figure 4.10.2.1 for the interrupt timing.

An underflow of timer 0 and timer 1 sets the corresponding interrupt factor flag IPT0 (timer 0) or IPT1 (timer 1) to "1", and generates an interrupt. The interrupt can also be masked by setting the corresponding interrupt mask register EIPT0 (timer 0) or EIPT1 (timer 1). However, the interrupt factor flag is set to "1" by an underflow of the corresponding timer regardless of the interrupt mask register setting.

### 4.10.6 Setting of TOUT output

The programmable timer can generate a TOUT signal due to an underflow of timer 0 or timer 1. The TOUT signal is generated by dividing the underflows in 1/2. It is possible to select which timer's underflow is to be used by the TOUT output channel selection register CHSEL. When "0" is written to the CHSEL register, timer 0 is selected and when "1" is written, timer 1 is selected.

Figure 4.10.6.1 shows the TOUT signal waveform when the channel is changed.

Fig. 4.10.6.1 TOUT signal waveform at channel change

The TOUT signal can be output from the R02 output port terminal. Programmable clocks can be supplied to external devices.

Figure 4.10.6.2 shows the configuration of the output port R02.

Fig. 4.10.6.2 Configuration of R02

The output of a TOUT signal is controlled by the PTOUT register. When "1" is written to the PTOUT register, the TOUT signal is output from the R02 output port terminal and when "0" is written, the terminal goes to a high (VDD) level. However, the data register R02 must always be "1" and the high impedance control register R02HIZ must always be "0" (data output state).

Since the TOUT signal is generated asynchronously from the PTOUT register, a hazard within 1/2 cycle is generated when the signal is turned ON and OFF by setting the register.

Figure 4.10.6.3 shows the output waveform of the TOUT signal.

Fig. 4.10.6.3 Output waveform of the TOUT signal

**4.10.7 Transfer rate setting for serial interface**

The signal that is made from underflows of timer 1 by dividing them in 1/2, can be used as the clock source for the serial interface.

The programmable timer outputs the clock to the serial interface by setting timer 1 into RUN state (PTRUN = "1"). It is not necessary to control with the PTOUT register.

Fig. 4.10.7.1 Synchronous clock of serial interface

A setting value for the RLD1X register according to a transfer rate is calculated by the following expression:

$$RLD1X = fosc / (32 * bps * \text{division ratio of the prescaler}) - 1$$

fosc: Oscillation frequency (OSC1/OSC3)  
 bps: Transfer rate  
 (00H can be set to RLD1X)

Be aware that the maximum clock frequency for the serial interface is limited to 1 MHz when OSC3 is used as the clock source.

## 4.10.8 I/O memory of programmable timer

Table 4.10.8.1 shows the I/O addresses and the control bits for the programmable timer.

Table 4.10.8.1 Control bits of programmable timer

Address	Register				Name	Init *1	1	0	Comment				
	D3	D2	D1	D0									
FFC0H	0	EVCNT	FCSEL	PLPOL	EVCNT	0	Event ct.	Timer	Unused Timer 0 counter mode selection

R		R/W		IPT0	0	Reset	Invalid	Interrupt factor flag (Programmable timer 0)					

\*1 Initial value at initial reset

\*3 Constantly "0" when being read

\*2 Not set in the circuit

**CKSEL0: Prescaler 0 source clock selection register (FFC1H•D0)**

**CKSEL1: Prescaler 1 source clock selection register (FFC1H•D1)**

Selects the source clock of the prescaler.

When "1" is written: OSC3 clock

When "0" is written: OSC1 clock

Reading: Valid

The source clock for the prescaler is selected from OSC1 or OSC3. When "0" is written to the CKSEL0 register, the OSC1 clock is selected as the input clock for the prescaler 0 (for timer 0) and when "1" is written, the OSC3 clock is selected.

Same as above, the source clock for prescaler 1 is selected by the CKSEL1 register.

When the event counter mode is selected to timer 0, the setting of the CKSEL0 register becomes invalid.

At initial reset, these registers are set to "0".

**PTPS00, PTPS01: Timer 0 prescaler division ratio selection register (FFC2H•D2, D3)**

**PTPS10, PTPS11: Timer 1 prescaler division ratio selection register (FFC3H•D2, D3)**

Selects the division ratio of the prescaler.

Two bits of PTPS00 and PTPS01 are the prescaler division ratio selection register for timer 0, and two bits of PTPS10 and PTPS11 are for timer 1. The prescaler division ratios that can be set by these registers are shown in Table 4.10.8.2.

*Table 4.10.8.2 Selection of prescaler division ratio*

PTPS11 PTPS01	PTPS10 PTPS00	Prescaler division ratio
1	1	Source clock / 256
1	0	Source clock / 32
0	1	Source clock / 4
0	0	Source clock / 1

When the event counter mode is selected to timer 0, the setting of the PTPS00 and PTPS01 becomes invalid.

At initial reset, these registers are set to "0".

**EVCNT: Timer 0 counter mode selection register (FFC0H•D2)**

Selects a counter mode for timer 0.

When "1" is written: Event counter mode

When "0" is written: Timer mode

Reading: Valid

The counter mode for timer 0 is selected from either the event counter mode or timer mode. When "1" is written to the EVCNT register, the event counter mode is selected and when "0" is written, the timer mode is selected.

At initial reset, this register is set to "0".

**FCSEL: Timer 0 function selection register (FFC0H•D1)**

Selects whether the noise rejector of the clock input circuit will be used or not in the event counter mode.

When "1" is written: With noise rejector

When "0" is written: Without noise rejector

Reading: Valid

When "1" is written to the FCSEL register, the noise rejector is used and counting is done by an external clock (K13) with 0.98 msec\* or more pulse width. The noise rejector allows the counter to input the clock at the second falling edge of the internal 2,048 Hz\* signal after changing the input level of the K13 input port terminal. Consequently, the pulse width of noise that can reliably be rejected is 0.48 msec\* or less. (\*:  $f_{OSC1} = 32.768$  kHz).

When "0" is written to the FCSEL register, the noise rejector is not used and the counting is done directly by an external clock input to the K13 input port terminal.

Setting of this register is effective only when timer 0 is used in the event counter mode.

At initial reset, this register is set to "0".

**PLPOL: Timer 0 pulse polarity selection register (FFC0H•D0)**

Selects the count pulse polarity in the event counter mode.

When "1" is written: Rising edge

When "0" is written: Falling edge

Reading: Valid

The count timing in the event counter mode (timer 0) is selected from either the falling edge of the external clock input to the K13 input port terminal or the rising edge. When "0" is written to the PLPOL register, the falling edge is selected and when "1" is written, the rising edge is selected.

Setting of this register is effective only when timer 0 is used in the event counter mode.

At initial reset, this register is set to "0".

**RLD00–RLD07: Timer 0 reload data register (FFC4H, FFC5H)****RLD10–RLD17: Timer 1 reload data register (FFC6H, FFC7H)**

Sets the initial value for the counter.

The reload data written in this register is loaded to the respective counters. The counter counts down using the data as the initial value for counting.

Reload data is loaded to the counter when the counter is reset by writing "1" to the PTRST0 or PTRST1 register, or when counter underflow occurs.

At initial reset, these registers are set to "00H".

**PTD00–PTD07: Timer 0 counter data (FFC8H, FFC9H)****PTD10–PTD17: Timer 1 counter data (FFCAH, FFCBH)**

Count data in the programmable timer can be read from these latches.

The low-order 4 bits of the count data in timer 0 can be read from PTD00–PTD03, and the high-order data can be read from PTD04–PTD07. Similarly, for timer 1, the low-order 4 bits can be read from PTD10–PTD13, and the high-order data can be read from PTD14–PTD17.

Since the high-order 4 bits are held by reading the low-order 4 bits, be sure to read the low-order 4 bits first.

Since these latches are exclusively for reading, the writing operation is invalid.

At initial reset, these counter data are set to "00H".

**PTRST0: Timer 0 reset (reload) (FFC2H•D1)**

**PTRST1: Timer 1 reset (reload) (FFC3H•D1)**

Resets the timer and presets reload data to the counter.

- When "1" is written: Reset
- When "0" is written: No operation
- Reading: Always "0"

By writing "1" to PTRST0, the reload data in the reload register PLD00–PLD07 is preset to the counter in timer 0. Similarly, the reload data in PLD10–PLD17 is preset to the counter in timer 1 by PTRST1.

When the counter is preset in the RUN status, the counter restarts immediately after presetting. In the case of STOP status, the reload data is preset to the counter and is maintained.

No operation results when "0" is written.

Since these bits are exclusively for writing, always set to "0" during reading.

**PTRUN0: Timer 0 RUN/STOP control register (FFC2H•D0)**

**PTRUN1: Timer 1 RUN/STOP control register (FFC3H•D0)**

Controls the RUN/STOP of the counter.

- When "1" is written: RUN
- When "0" is written: STOP
- Reading: Valid

The counter in timer 0 starts counting down by writing "1" to the PTRUN0 register and stops by writing "0".

In STOP status, the counter data is maintained until the counter is reset or is set in the next RUN status. When STOP status changes to RUN status, the data that has been maintained can be used for resuming the count.

Same as above, the timer 1 counter is controlled by the PTRUN1 register.

At initial reset, these registers are set to "0".

**CHSEL: TOUT output channel selection register (FFC1H•D3)**

Selects the channel used for TOUT signal output.

- When "1" is written: Timer 1
- When "0" is written: Timer 0
- Reading: Valid

This register selects which timer's underflow (timer 0 or timer 1) is used to generate a TOUT signal. When "0" is written to the CHSEL register, timer 0 is selected and when "1" is written, timer 1 is selected.

At initial reset, this register is set to "0".

**PTOUT: TOUT output control register (FFC1H•D2)**

Turns TOUT signal output ON and OFF.

- When "1" is written: ON
- When "0" is written: OFF
- Reading: Valid

PTOUT is the output control register for the TOUT signal. When "1" is written to the register, the TOUT signal is output from the output port terminal R02 and when "0" is written, the terminal goes to a high (VDD) level. However, the data register R02 must always be "1" and the high impedance control register R02HIZ must always be "0" (data output state).

At initial reset, this register is set to "0".

**EIPT0: Timer 0 interrupt mask register (FFE2H•D0)****EIPT1: Timer 1 interrupt mask register (FFE2H•D1)**

These registers are used to select whether to mask the programmable timer interrupt or not.

When "1" is written: Enabled

When "0" is written: Masked

Reading: Valid

Timer 0 and timer 1 interrupts can be masked individually by the interrupt mask registers EIPT0 (timer 0) and EIPT1 (timer 1).

At initial reset, these registers are set to "0".

**IPT0: Timer 0 interrupt factor flag (FFF2H•D0)****IPT1: Timer 1 interrupt factor flag (FFF2H•D1)**

These flags indicate the status of the programmable timer interrupt.

When "1" is read: Interrupt has occurred

When "0" is read: Interrupt has not occurred

When "1" is written: Flag is reset

When "0" is written: Invalid

The interrupt factor flags IPT0 and IPT1 correspond to timer 0 and timer 1 interrupts, respectively. The software can judge from these flags whether there is a programmable timer interrupt. However, even if the interrupt is masked, the flags are set to "1" by the underflows of the corresponding counters.

These flags are reset to "0" by writing "1" to them.

After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.

At initial reset, these flags are set to "0".

**4.10.9 Programming notes**

- (1) When reading counter data, be sure to read the low-order 4 bits (PTD00–PTD03, PTD10–PTD13) first. Furthermore, the high-order 4 bits (PTD04–PTD07, PTD14–PTD17) should be read within 0.73 msec (when fOSC1 is 32.768 kHz) of reading the low-order 4 bits (PTD00–PTD03, PTD10–PTD13).
- (2) The programmable timer actually enters RUN/STOP status in synchronization with the falling edge of the input clock after writing to the PTRUN0/PTRUN1 register. Consequently, when "0" is written to the PTRUN0/PTRUN1 register, the timer enters STOP status at the point where the counter is decremented (-1). The PTRUN0/PTRUN1 register maintains "1" for reading until the timer actually stops.

Figure 4.10.9.1 shows the timing chart for the RUN/STOP control.

*Fig. 4.10.9.1 Timing chart for RUN/STOP control*

It is the same even in the event counter mode. Therefore, be aware that the counter does not enter RUN/STOP status if a clock is not input after setting the RUN/STOP control register (PTRUN0).

- (3) Since the TOUT signal is generated asynchronously from the PTOUT register, a hazard within 1/2 cycle is generated when the signal is turned ON and OFF by setting the register.
- (4) When the OSC3 oscillation clock is selected for the clock source, it is necessary to turn the OSC3 oscillation ON, prior to using the programmable timer. However the OSC3 oscillation circuit requires a time at least 5 msec from turning the circuit ON until the oscillation stabilizes. Therefore, allow an adequate interval from turning the OSC3 oscillation circuit ON to starting the programmable timer. Refer to Section 4.3, "Oscillation Circuit", for the control and notes of the OSC3 oscillation circuit. At initial reset, the OSC3 oscillation circuit is set in the OFF state.
- (5) After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.

## 4.11 Serial Interface

### 4.11.1 Configuration of serial interface

The E0C63567 incorporates a full duplex serial interface (when asynchronous system is selected) that allows the user to select either clock synchronous system or asynchronous system.

The data transfer method can be selected in software.

When the clock synchronous system is selected, 8-bit data transfer is possible.

When the asynchronous system is selected, either 7-bit or 8-bit data transfer is possible, and a parity check of received data and the addition of a parity bit for transmitting data can automatically be done by selecting in software.

Figure 4.11.1.1 shows the configuration of the serial interface.

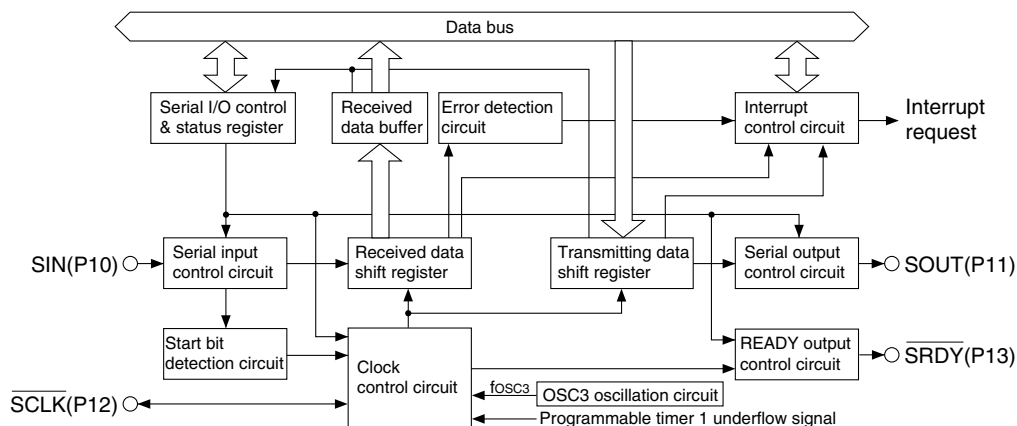

Fig. 4.11.1.1 Configuration of serial interface

Serial interface input/output terminals, SIN, SOUT,  $\overline{\text{SCLK}}$  and  $\overline{\text{SRDY}}$  are shared with the I/O ports P10–P13. In order to utilize these terminals for the serial interface input/output terminals, proper settings have to be made with registers ESIF, SMD0 and SMD1. (At initial reset, these terminals are set as I/O port terminals.)

The direction of I/O port terminals set for serial interface input/output terminals are determined by the signal and transfer mode for each terminal. Furthermore, the settings for the corresponding I/O control registers for the I/O ports become invalid.

Table 4.11.1.1 Configuration of input/output terminals

Terminal	When serial interface is selected
P10	SIN
P11	SOUT
P12	$\overline{\text{SCLK}}$
P13	$\overline{\text{SRDY}}$

\* The terminals used may vary depending on the transfer mode.

SIN and SOUT are serial data input and output terminals which function identically in clock synchronous system and asynchronous system.  $\overline{\text{SCLK}}$  is exclusively for use with clock synchronous system and functions as a synchronous clock input/output terminal.  $\overline{\text{SRDY}}$  is exclusively for use in clock synchronous slave mode and functions as a send-receive ready signal output terminal.

When asynchronous system is selected, since  $\overline{\text{SCLK}}$  and  $\overline{\text{SRDY}}$  are superfluous, the I/O port terminals P12 and P13 can be used as I/O ports.

In the same way, when clock synchronous master mode is selected, since  $\overline{\text{SRDY}}$  is superfluous, the I/O port terminal P13 can be used as I/O port.

### 4.11.2 Mask option

Since the input/output terminals of the serial interface is shared with the I/O ports (P10–P13), the mask option that selects the output specification for the I/O port is also applied to the serial interface. The output specification of the terminals SOUT,  $\overline{\text{SCLK}}$  (for clock synchronous master mode) and  $\overline{\text{SRDY}}$  (for clock synchronous slave mode) that are used as output in the input/output port of the serial interface is respectively selected by the mask options of P11, P12 and P13. Either complementary output or N-channel open drain output can be selected as the output specification. However, when N-channel open drain output is selected, do not apply a voltage exceeding the power supply voltage to the terminal.

Furthermore, the pull-up resistor for the SIN terminal and the  $\overline{\text{SCLK}}$  terminal (for clock synchronous slave mode) that are used as input terminals can be selected by the mask options of P10 and P12. When "without pull-up" is selected, take care that the floating status does not occur.

### 4.11.3 Transfer modes

There are four transfer modes for the serial interface and mode selection is made by setting the two bits of the mode selection registers SMD0 and SMD1 as shown in the table below.

Table 4.11.3.1 Transfer modes

SMD1	SMD0	Mode
1	1	8-bit asynchronous
1	0	7-bit asynchronous
0	1	Clock synchronous slave
0	0	Clock synchronous master

Table 4.11.3.2 Terminal settings corresponding to each transfer mode

Mode	SIN	SOUT	$\overline{\text{SCLK}}$	$\overline{\text{SRDY}}$
Asynchronous 8-bit	Input	Output	P12	P13
Asynchronous 7-bit	Input	Output	P12	P13
Clock synchronous slave	Input	Output	Input	Output
Clock synchronous master	Input	Output	Output	P13

At initial reset, transfer mode is set to clock synchronous master mode.

#### Clock synchronous master mode

In this mode, the internal clock is utilized as a synchronous clock for the built-in shift registers, and 8-bit clock synchronous serial transfers can be performed with this serial interface as the master.

The synchronous clock is also output from the  $\overline{\text{SCLK}}$  terminal which enables control of the external (slave side) serial I/O device. Since the  $\overline{\text{SRDY}}$  terminal is not utilized in this mode, it can be used as an I/O port.

Figure 4.11.3.1(a) shows the connection example of input/output terminals in the clock synchronous master mode.

#### Clock synchronous slave mode

In this mode, a synchronous clock from the external (master side) serial input/output device is utilized and 8-bit clock synchronous serial transfers can be performed with this serial interface as the slave.

The synchronous clock is input to the  $\overline{\text{SCLK}}$  terminal and is utilized by this interface as the synchronous clock.

Furthermore, the  $\overline{\text{SRDY}}$  signal indicating the transmit-receive ready status is output from the  $\overline{\text{SRDY}}$  terminal in accordance with the serial interface operating status.

In the slave mode, the settings for registers SCS0 and SCS1 used to select the clock source are invalid. Figure 4.11.3.1(b) shows the connection example of input/output terminals in the clock synchronous slave mode.

**7-bit asynchronous mode**

In this mode, 7-bit asynchronous transfer can be performed. Parity check during data reception and addition of parity bit (odd/even/none) during transmitting can be specified and data processed in 7 bits with or without parity. Since this mode employs the internal clock, the  $\overline{\text{SCLK}}$  terminal is not used. Furthermore, since the  $\overline{\text{SRDY}}$  terminal is not utilized either, both of these terminals can be used as I/O ports.

Figure 4.11.3.1(c) shows the connection example of input/output terminals in the asynchronous mode.

**8-bit asynchronous 8-bit mode**

In this mode, 8-bit asynchronous transfer can be performed. Parity check during data reception and addition of parity bit (odd/even/none) during transmitting can be specified and data processed in 8 bits with or without parity. Since this mode employs the internal clock, the  $\overline{\text{SCLK}}$  terminal is not used. Furthermore, since the  $\overline{\text{SRDY}}$  terminal is not utilized either, both of these terminals can be used as I/O ports.

Figure 4.11.3.1(c) shows the connection example of input/output terminals in the asynchronous mode.

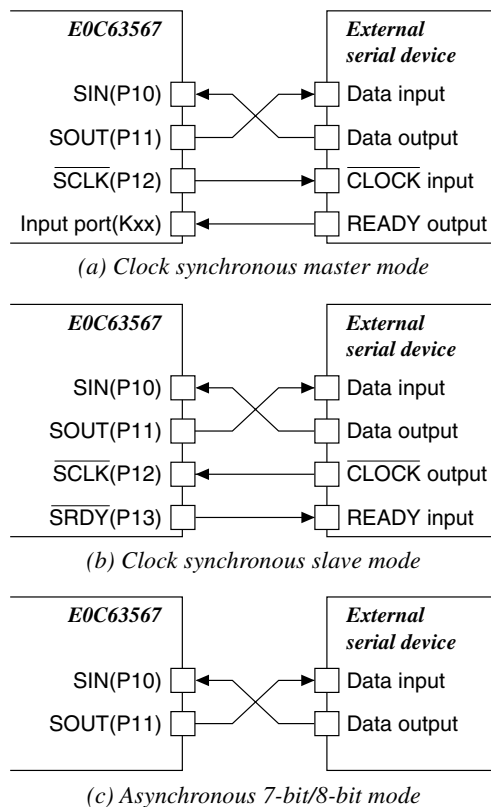

Fig. 4.11.3.1 Connection examples of serial interface I/O terminals

4.11.4 Clock source

There are four clock sources and selection is made by setting the two bits of the clock source selection register SCS0 and SCS1 as shown in table below.

Table 4.11.4.1 Clock source

SCS1	SCS0	Clock source
1	1	Programmable timer
1	0	fosc3 / 93
0	1	fosc3 / 372
0	0	fosc3 / 186

This register setting is invalid in clock synchronous slave mode and the external clock input from the SCLK terminal is used.

When the "programmable timer" is selected, the programmable timer 1 underflow signal is divided by 1/2 and this signal used as the clock source. With respect to the transfer rate setting, see "4.10 Programmable Timer". At initial reset, the synchronous clock is set to "fosc3/186".

Whichever clock is selected, the signal is further divided by 1/16 and then used as the synchronous clock. Furthermore, external clock input is used as is for SCLK in clock synchronous slave mode.

Fig. 4.11.4.1 Division of the synchronous clock

Table 4.11.4.2 shows an examples of transfer rates and OSC3 oscillation frequencies when the clock source is set to programmable timer.

Table 4.11.4.2 OSC3 oscillation frequencies and transfer rates

Transfer rate (bps)	fosc3 = 3.580 MHz	
	PSC1X	RLD1X
9,600	0 (1/1)	0CH
4,800	0 (1/1)	17H
2,400	0 (1/1)	2FH
1,200	0 (1/1)	5DH
600	0 (1/1)	BAH
300	1 (1/4)	5DH
150	1 (1/4)	BAH

When the demultiplied signal of the OSC3 oscillation circuit is made the clock source, it is necessary to turn the OSC3 oscillation ON, prior to using the serial interface.

A time interval of several msec to several 10 msec, from the turning ON of the OSC3 oscillation circuit to until the oscillation stabilizes, is necessary, due to the oscillation element that is used. Consequently, you should allow an adequate waiting time after turning ON of the OSC3 oscillation, before starting transmitting/receiving of serial interface. (The oscillation start time will vary somewhat depending on the oscillator and on the externally attached parts. Refer to the oscillation start time example indicated in Chapter 7, "Electrical Characteristics".)

At initial reset, the OSC3 oscillation circuit is set to OFF status.

### 4.11.5 Transmit-receive control

Below is a description of the registers which handle transmit-receive control. With respect to transmit-receive control procedures and operations, please refer to the following sections in which these are discussed on a mode by mode basis.

#### Shift register and receive data buffer

Exclusive shift registers for transmitting and receiving are installed in this serial interface. Consequently, duplex communication simultaneous transmit and receive is possible when the asynchronous system is selected.

Data being transmitted are written to TRXD0–TRXD7 and converted to serial through the shift register and is output from the SOUT terminal.

In the reception section, a receive data buffer is installed separate from the shift register.

Data being received are input to the SIN terminal and is converted to parallel through the shift register and written to the receive data buffer.

Since the receive data buffer can be read even during serial input operation, the continuous data is received efficiently.

However, since buffer functions are not used in clock synchronous mode, be sure to read out data before the next data reception begins.

#### Transmit enable register and transmit control bit

For transmit control, use the transmit enable register TXEN and transmit control bit TXTRG.

The transmit enable register TXEN is used to set the transmit enable/disable status. When "1" is written to this register to set the transmitting enable status, clock input to the shift register is enabled and the system is ready to transmit data. In the clock synchronous mode, synchronous clock input/output from the SCLK terminal is also enabled.

The transmit control bit TXTRG is used as the trigger to start transmitting data.

Data to be transmitted is written to the transmit data shift register, and when transmitting preparations are complete, "1" is written to TXTRG whereupon data transmitting begins.

When interrupt has been enabled, an interrupt is generated when the transmission is completed. If there is subsequent data to be transmitted it can be sent using this interrupt.

In addition, TXTRG can be read as a status bit. When set to "1", it indicates transmitting operation, and "0" indicates transmitting stop.

For details on timing, see the timing chart which gives the timing for each mode.

When not transmitting, set TXEN to "0" to disable transmission.

#### Receive enable register, receive control bit

For receiving control, use the receive enable register RXEN and receive control bit RXTRG.

Receive enable register RXEN is used to set receiving enable/disable status. When "1" is written into this register to set the receiving enable status, clock input to the shift register is enabled and the system is ready to receive data. In the clock synchronous mode, synchronous clock input/output from the SCLK terminal is also enabled.

With the above setting, receiving begins and serial data input from the SIN terminal goes to the shift register.

The operation of the receive control bit RXTRG is slightly different depending on whether a clock synchronous system or an asynchronous system is being used.

In the clock synchronous system, the receive control bit RXTRG is used as the trigger to start receiving data.

When received data has been read and the preparation for next data receiving is completed, write "1" into RXTRG to start receiving. (When "1" is written to RXTRG in slave mode, SRDY switches to "0".)

In an asynchronous system, RXTRG is used to prepare for next data receiving. After reading the received data from the receive data buffer, write "1" into RXTRG to signify that the receive data buffer is empty. If "1" is not written into RXTRG, the overrun error flag OER will be set to "1" when the next receiving operation is completed. (An overrun error will be generated when receiving is completed between reading the received data and the writing of "1" to RXTRG.)

In addition, RXTRG can be read as a status bit. In either clock synchronous mode or asynchronous mode, when RXTRG is set to "1", it indicates receiving operation and when set to "0", it indicates that receiving has stopped.

For details on timing, see the timing chart which gives the timing for each mode.

When you do not receive, set RXEN to "0" to disable receiving.

#### 4.11.6 Operation of clock synchronous transfer

Clock synchronous transfer involves the transfer of 8-bit data by synchronizing it to eight clocks. The same synchronous clock is used by both the transmitting and receiving sides.

When the serial interface is used in the master mode, the clock signal selected using SCS0 and SCS1 is further divided by 1/16 and employed as the synchronous clock. This signal is then sent via the  $\overline{\text{SCLK}}$  terminal to the slave side (external serial I/O device).

When used in the slave mode, the clock input to the  $\overline{\text{SCLK}}$  terminal from the master side (external serial input/output device) is used as the synchronous clock.

In the clock synchronous mode, since one clock line ( $\overline{\text{SCLK}}$ ) is shared for both transmitting and receiving, transmitting and receiving cannot be performed simultaneously. (Half duplex only is possible in clock synchronous mode.)

Transfer data is fixed at 8 bits and both transmitting and receiving are conducted with the LSB (bit 0) coming first.

Fig. 4.11.6.1 Transfer data configuration using clock synchronous mode

Below is a description of initialization when performing clock synchronous transfer, transmit-receive control procedures and operations.

With respect to serial interface interrupt, see "4.11.8 Interrupt function".

#### Initialization of serial interface

When performing clock synchronous transfer, the following initial settings must be made.

##### (1) Setting of transmitting/receiving disable

To set the serial interface into a status in which both transmitting and receiving are disabled, "0" must be written to both the transmit enable register TXEN and the receive enable register RXEN. Fix these two registers to a disable status until data transfer actually begins.

##### (2) Port selection

Because serial interface input/output ports SIN, SOUT,  $\overline{\text{SCLK}}$  and  $\overline{\text{SRDY}}$  are set as I/O port terminals P10–P13 at initial reset, "1" must be written to the serial interface enable register ESIF in order to set these terminals for serial interface use.

##### (3) Setting of transfer mode

Select the clock synchronous mode by writing the data as indicated below to the two bits of the mode selection registers SMD0 and SMD1.

Master mode: SMD0 = "0", SMD1 = "0"

Slave mode: SMD0 = "1", SMD1 = "0"

## (4) Clock source selection

In the master mode, select the synchronous clock source by writing data to the two bits of the clock source selection registers SCS0 and SCS1. (See Table 4.11.4.1.)

This selection is not necessary in the slave mode.

The parity enable register EPR is also assigned to this address, however, since parity is not necessary in the clock synchronous mode, parity check will not take place regardless of how they are set.

## (5) Clock source control

When the master mode is selected and programmable timer for the clock source is selected, set transfer rate on the programmable timer side. (See "4.10 Programmable Timer".)

When the divided signal of OSC3 oscillation circuit is selected for the clock source, be sure that the OSC3 oscillation circuit is turned ON prior to commencing data transfer. (See "4.3 Oscillation Circuit".)

Note that the frequency of the serial interface clock is limited to a maximum of 1 MHz.

**Data transmit procedure**

The control procedure and operation during transmitting is as follows.

- (1) Write "0" in the transmit enable register TXEN and the receive enable register RXEN to reset the serial interface.
- (2) Write "1" in the transmit enable register TXEN to set into the transmitting enable status.
- (3) Write the transmitting data into TRXD0–TRXD7.
- (4) In case of the master mode, confirm the receive ready status on the slave side (external serial input/output device), if necessary. Wait until it reaches the receive ready status.
- (5) Write "1" in the transmit control bit TXTRG and start transmitting.

In the master mode, this control causes the synchronous clock to change to enable and to be provided to the shift register for transmitting and output from the  $\overline{\text{SCLK}}$  terminal.

In the slave mode, it waits for the synchronous clock to be input from the  $\overline{\text{SCLK}}$  terminal.

The transmitting data of the shift register shifts one bit at a time at each falling edge of the synchronous clock and is output from the SOUT terminal. When the final bit (MSB) is output, the SOUT terminal is maintained at that level, until the next transmitting begins.

The transmitting complete interrupt factor flag ISTR is set to "1" at the point where the data transmitting of the shift register is completed. When interrupt has been enabled, a transmitting complete interrupt is generated at this point.

Set the following transmitting data using this interrupt.

- (6) Repeat steps (3) to (5) for the number of bytes of transmitting data, and then set the transmit disable status by writing "0" to the transmit enable register TXEN, when the transmitting is completed.

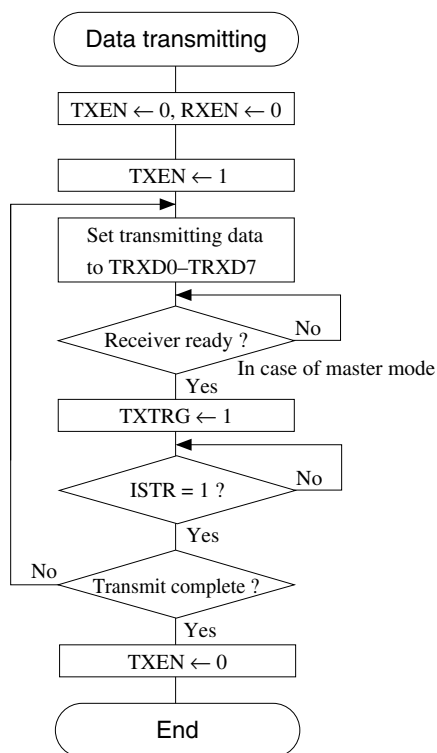

Fig. 4.11.6.2 Transmit procedure in clock synchronous mode

**Data receive procedure**

The control procedure and operation during receiving is as follows.

- (1) Write "0" in the receive enable register RXEN and transmit enable register TXEN to reset the serial interface.
- (2) Write "1" in the receive enable register RXEN to set into the receiving enable status.
- (3) In case of the master mode, confirm the transmit ready status on the slave side (external serial input/output device), if necessary. Wait until it reaches the transmit ready status.
- (4) Write "1" in the receive control bit RXTRG and start receiving.

In the master mode, this control causes the synchronous clock to change to enable and is provided to the shift register for receiving and output from the  $\overline{SCLK}$  terminal.

In the slave mode, it waits for the synchronous clock to be input from the  $\overline{SCLK}$  terminal. The received data input from the SIN terminal is successively incorporated into the shift register in synchronization with the rising edge of the synchronous clock.

At the point where the data of the 8th bit has been incorporated at the final (8th) rising edge of the synchronous clock, the content of the shift register is sent to the receive data buffer and the receiving complete interrupt factor flag ISRC is set to "1". When interrupt has been enabled, a receiving complete interrupt is generated at this point.

- (5) Read the received data from TRXD0–TRXD7 using receiving complete interrupt.
- (6) Repeat steps (3) to (5) for the number of bytes of receiving data, and then set the receive disable status by writing "0" to the receive enable register RXEN, when the receiving is completed.

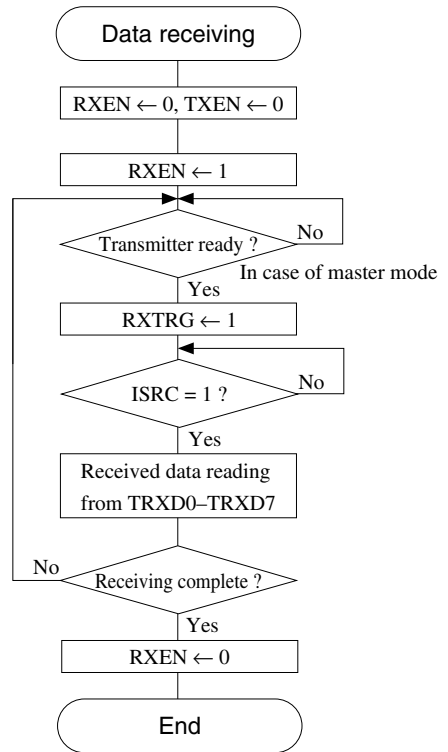

Fig. 4.11.6.3 Receiving procedure in clock synchronous mode

**Transmit/receive ready (SRDY) signal**

When this serial interface is used in the clock synchronous slave mode (external clock input), an  $\overline{\text{SRDY}}$  signal is output to indicate whether or not this serial interface can transmit/receive to the master side (external serial input/output device). This signal is output from the  $\overline{\text{SRDY}}$  terminal and when this interface enters the transmit or receive enable (READY) status, it becomes "0" (Low level) and becomes "1" (High level) when there is a BUSY status, such as during transmit/receive operation. The  $\overline{\text{SRDY}}$  signal changes the "1" to "0," immediately after writing "1" into the transmit control bit TXTRG or the receive control bit RXTRG and returns from "0" to "1", at the point where the first synchronous clock has been input (falling edge).

When you have set in the master mode, control the transfer by inputting the same signal from the slave side using the input port or I/O port. At this time, since the  $\overline{\text{SRDY}}$  terminal is not set and instead P13 functions as the I/O port, you can apply this port for said control.

**Timing chart**

The timing chart for the clock synchronous system transmission is shown in Figure 4.11.6.4.

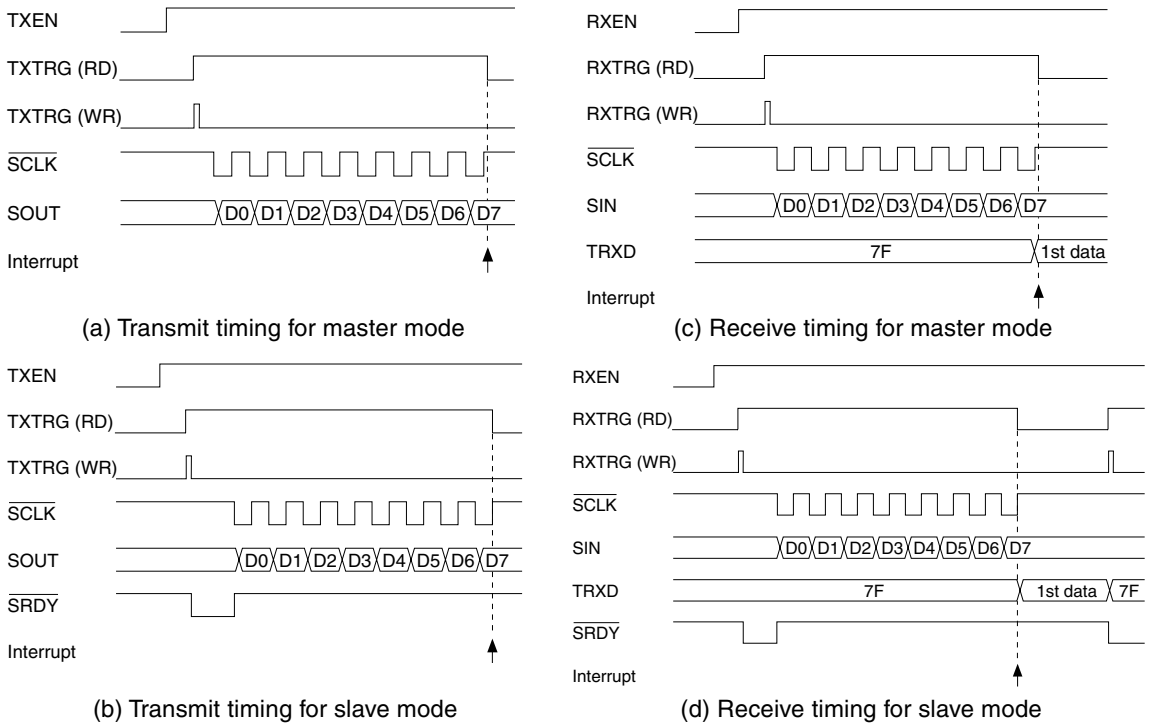

Fig. 4.11.6.4 Timing chart (clock synchronous system transmission)

### 4.11.7 Operation of asynchronous transfer

Asynchronous transfer is a mode that transfers by adding a start bit and a stop bit to the front and the back of each piece of serial converted data. In this mode, there is no need to use a clock that is fully synchronized clock on the transmit side and the receive side, but rather transmission is done while adopting the synchronization at the start/stop bits that have attached before and after each piece of data. The RS-232C interface functions can be easily realized by selecting this transfer mode.

This interface has separate transmit and receive shift registers and is designed to permit full duplex transmission to be done simultaneously for transmitting and receiving.

For transfer data in the 7-bit asynchronous mode, either 7 bits data (no parity) or 7 bits data + parity bit can be selected. In the 8-bit asynchronous mode, either 8 bits data (no parity) or 8 bits data + parity bit can be selected.

Parity can be even or odd, and parity checking of received data and adding a party bit to transmitting data will be done automatically. Thereafter, it is not necessary to be conscious of parity itself in the program.

The start bit and stop bit are respectively fixed at one bit and data is transmitted and received by placing the LSB (bit 0) at the front.

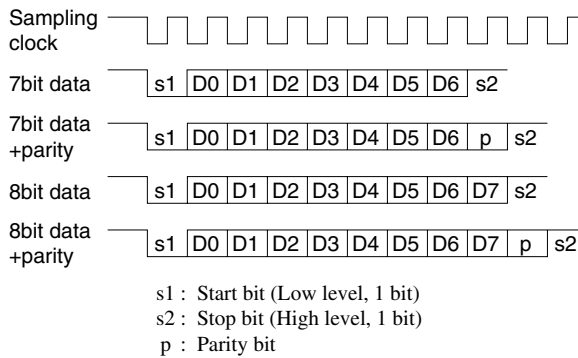

Fig. 4.11.7.1 Transfer data configuration for asynchronous system

Here following, we will explain the control sequence and operation for initialization and transmitting / receiving in case of asynchronous data transfer. See "4.11.8 Interrupt function" for the serial interface interrupts.

#### Initialization of serial interface

The below initialization must be done in cases of asynchronous system transfer.

(1) Setting of transmitting/receiving disable

To set the serial interface into a status in which both transmitting and receiving are disabled, "0" must be written to both the transmit enable register TXEN and the receive enable register RXEN. Fix these two registers to a disable status until data transfer actually begins.

(2) Port selection

Because serial interface input/output terminals SIN and SOUT are set as I/O port terminals P10 and P11 at initial reset, "1" must be written to the serial interface enable register ESIF in order to set these terminals for serial interface use.

SCLK and SRDY terminals set in the clock synchronous mode are not used in the asynchronous mode. These terminals function as I/O port terminals P12 and P13.

(3) Setting of transfer mode

Select the asynchronous mode by writing the data as indicated below to the two bits of the mode selection registers SMD0 and SMD1.

7-bit mode: SMD0 = "0", SMD1 = "1"

8-bit mode: SMD0 = "1", SMD1 = "1"

## (4) Parity bit selection

When checking and adding parity bits, write "1" into the parity enable register EPR to set to "with parity check". As a result of this setting, in the 7-bit asynchronous mode, it has a 7 bits data + parity bit configuration and in the 8-bit asynchronous mode it has an 8 bits data + parity bit configuration. In this case, parity checking for receiving and adding a parity bit for transmitting is done automatically in hardware. Moreover, when "with parity check" has been selected, "odd" or "even" parity must be further selected in the parity mode selection register PMD.

When "0" is written to the PMD register to select "without parity check" in the 7-bit asynchronous mode, data configuration is set to 7 bits data (no parity) and in the 8-bit asynchronous mode (no parity) it is set to 8 bits data (no parity) and parity checking and parity bit adding will not be done.

## (5) Clock source selection

Select the clock source by writing data to the two bits of the clock source selection registers SCS0 and SCS1. (See Table 4.11.4.1.)

## (6) Clock source control

When the programmable timer is selected for the clock source, set transfer rate on the programmable timer side. (See "4.10 Programmable Timer".)

When the divided signal of OSC3 oscillation circuit is selected for the clock source, be sure that the OSC3 oscillation circuit is turned ON prior to commencing data transfer. (See "4.3 Oscillation Circuit".)

**Data transmit procedure**

The control procedure and operation during transmitting is as follows.

- (1) Write "0" in the transmit enable register TXEN to reset the serial interface.

- (2) Write "1" in the transmit enable register TXEN to set into the transmitting enable status.

- (3) Write the transmitting data into TRXD0–TRXD7.  
Also, when 7-bit data is selected, the TRXD7 data becomes invalid.

- (4) Write "1" in the transmit control bit TXTRG and start transmitting.

This control causes the shift clock to change to enable and a start bit (LOW) is output to the SOUT terminal in synchronize to its rising edge. The transmitting data set to the shift register is shifted one bit at a time at each rising edge of the clock thereafter and is output from the SOUT terminal. After the data output, it outputs a stop bit (HIGH) and HIGH level is maintained until the next start bit is output.

The transmitting complete interrupt factor flag ISTR is set to "1" at the point where the data transmitting is completed. When interrupt has been enabled, a transmitting complete interrupt is generated at this point.

Set the following transmitting data using this interrupt.

- (5) Repeat steps (3) to (4) for the number of bytes of transmitting data, and then set the transmit disable status by writing "0" to the transmit enable register TXEN, when the transmitting is completed.

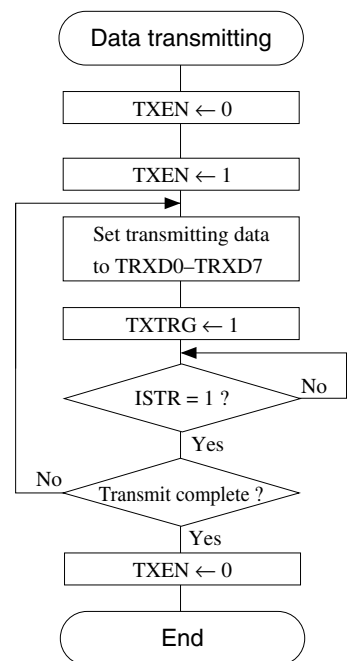

Fig. 4.11.7.2 Transmit procedure in asynchronous mode

**Data receive procedure**

The control procedure and operation during receiving is as follows.

- (1) Write "0" in the receive enable register RXEN to set the receiving disable status and to reset the respective PER, OER, FER flags that indicate parity, overrun and framing errors.
- (2) Write "1" in the receive enable register RXEN to set into the receiving enable status.
- (3) The shift clock will change to enable from the point where the start bit (LOW) has been input from the SIN terminal and the receive data will be synchronized to the rising edge following the second clock, and will thus be successively incorporated into the shift register.

After data bits have been incorporated, the stop bit is checked and, if it is not HIGH, it becomes a framing error and the error interrupt factor flag ISER is set to "1". When interrupt has been enabled, an error interrupt is generated at this point. When receiving is completed, data in the shift register is transferred to the receive data buffer and the receiving complete interrupt flag ISRC is set to "1". When interrupt has been enabled, a receiving complete interrupt is generated at this point. (When an overrun error is generated, the interrupt factor flag ISRC is not set to "1" and a receiving complete interrupt is not generated.)

If "with parity check" has been selected, a parity check is executed when data is transferred into the receive data buffer from the shift register and if a parity error is detected, the error interrupt factor flag is set to "1". When the interrupt has been enabled, an error interrupt is generated at this point just as in the framing error mentioned above.

- (4) Read the received data from TRXD0–TRXD7 using receiving complete interrupt.
- (5) Write "1" to the receive control bit RXTRG to inform that the receive data has been read out. When the following data is received prior to writing "1" to RXTRG, it is recognized as an overrun error and the error interrupt factor flag is set to "1". When the interrupt has been enabled, an error interrupt is generated at this point just as in the framing error and parity error mentioned above.
- (6) Repeat steps (3) to (5) for the number of bytes of receiving data, and then set the receive disable status by writing "0" to the receive enable register RXEN, when the receiving is completed.

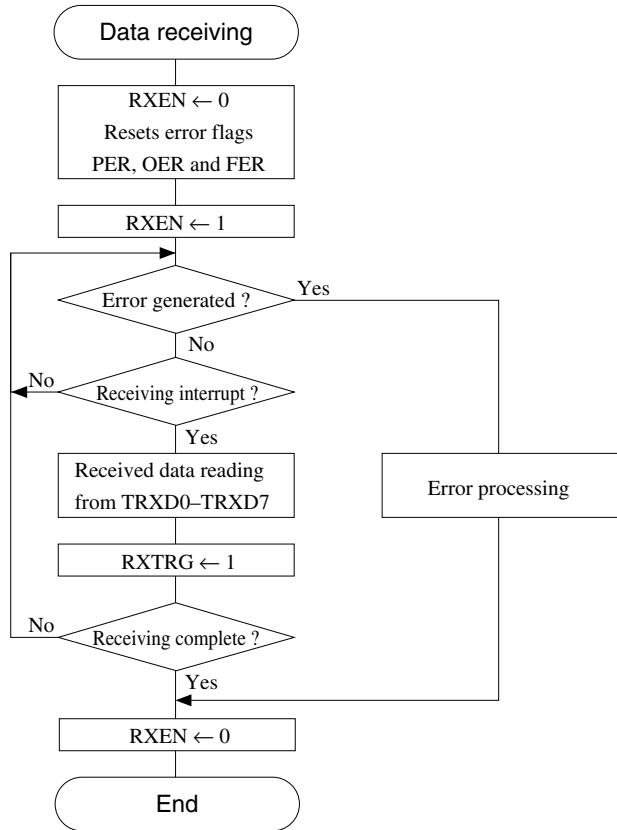

Fig. 4.11.7.3 Receiving procedure in asynchronous mode

**Receive error**

During receiving the following three types of errors can be detected by an interrupt.

**(1) Parity error**

When writing "1" to the EPR register to select "with parity check", a parity check (vertical parity check) is executed during receiving. After each data bit is sent a parity check bit is sent. The parity check bit is a "0" or a "1". Even parity checking will cause the sum of the parity bit and the other bits to be even. Odd parity causes the sum to be odd. This is checked on the receiving side.

The parity check is performed when data received in the shift register is transferred to the receive data buffer. It checks whether the parity check bit is a "1" or a "0" (the sum of the bits including the parity bit) and the parity set in the PMD register match. When it does not match, it is recognized as an parity error and the parity error flag PER and the error interrupt factor flag ISER is set to "1". When interrupt has been enabled, an error interrupt is generated at this point.

The PER flag is reset to "0" by writing "1".

Even when this error has been generated, the received data corresponding to the error is transferred in the receive data buffer and the receive operation also continues.

The received data at this point cannot assured because of the parity error.

**(2) Framing error**

In asynchronous transfer, synchronization is adopted for each character at the start bit ("0") and the stop bit ("1"). When receiving has been done with the stop bit set at "0", the serial interface judges the synchronization to be off and a framing error is generated. When this error is generated, the framing error flag FER and the error interrupt factor flag ISER are set to "1". When interrupt has been enabled, an error interrupt is generated at this point.

The FER flag is reset to "0" by writing "1".

Even when this error has been generated, the received data for it is loaded into the receive data buffer and the receive operation also continues. However, even when it does not become a framing error with the following data receipt, such data cannot be assured.

Even when this error has been generated, the received data corresponding to the error is transferred in the receive data buffer and the receive operation also continues. However, even when it does not become a framing error with the following data receiving, such data cannot be assured.

**(3) Overrun error**

When the next data is received before "1" is written to RXTRG, an overrun error will be generated, because the previous receive data will be overwritten. When this error is generated, the overrun error flag OER and the error interrupt factor flag ISER are set to "1". When interrupt has been enabled, an error interrupt is generated at this point. The OER flag is reset to "0" by writing "1" into it.

Even when this error has been generated, the received data corresponding to the error is transferred in the receive data buffer and the receive operation also continues.

Furthermore, when the timing for writing "1" to RXTRG and the timing for the received data transfer to the receive data buffer overlap, it will be recognized as an overrun error.

**Timing chart**

Figure 4.11.7.4 show the asynchronous transfer timing chart.

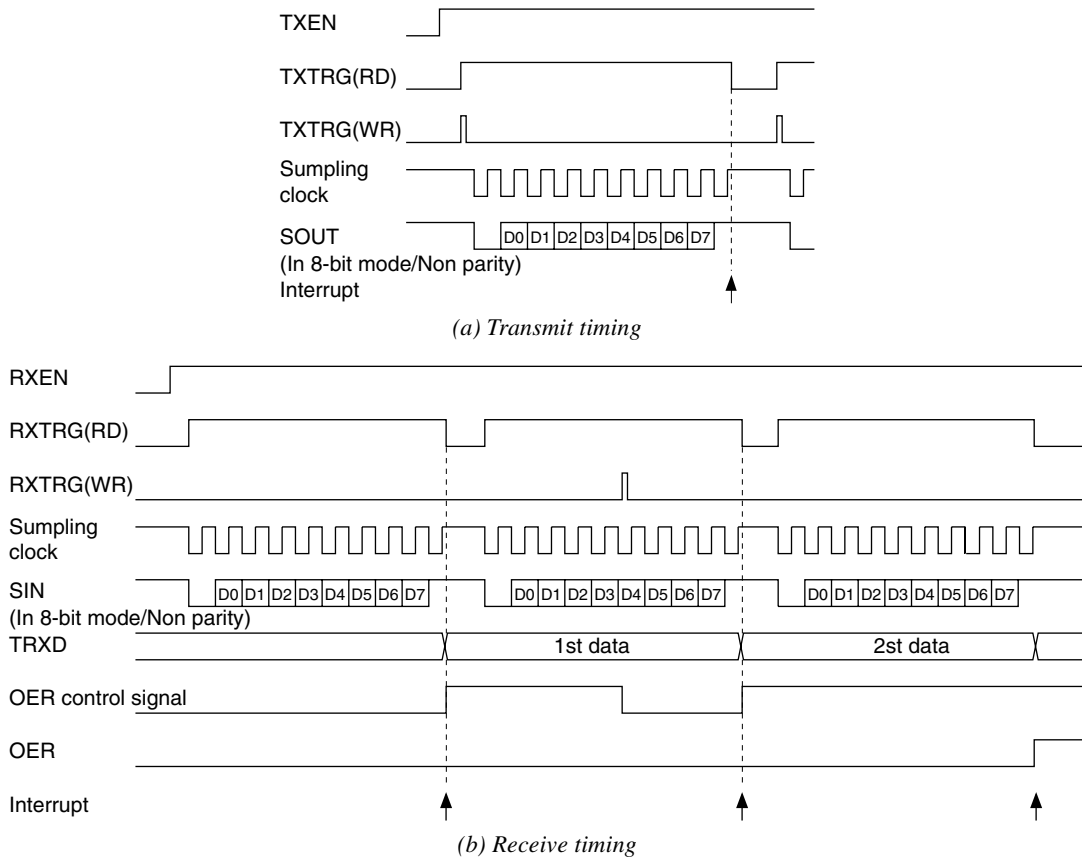

Fig. 4.11.7.4 Timing chart (asynchronous transfer)

**4.11.8 Interrupt function**

This serial interface includes a function that generates the below indicated three types of interrupts.

- Transmitting complete interrupt
- Receiving complete interrupt
- Error interrupt

The interrupt factor flag ISxx and the interrupt mask register EISxx for the respective interrupt factors are provided and then the interrupt can be disabled/enabled by the software.

Figure 4.11.8.1 shows the configuration of the serial interface interrupt circuit.

Fig. 4.11.8.1 Configuration of serial interface interrupt circuit

### Transmit completion interrupt

This interrupt factor is generated at the point where the sending of the data written into the shift register has been completed and sets the interrupt factor flag ISTR to "1". When set in this manner, if the corresponding interrupt mask register EISTR is set to "1" and the CPU is set to interrupt enabled status (I flag = "1"), an interrupt will be generated to the CPU.

When the interrupt mask register EISTR has been set to "0" and interrupt has been disabled, no interrupt is generated to the CPU. Even in this case, the interrupt factor flag ISTR is set to "1".

The interrupt factor flag ISTR is reset to "0" by writing "1".

The following transmitting data can be set and the transmitting can be started (writing "1" to TXTRG) after this interrupt factor occurs.

### Receive completion interrupt

This interrupt factor is generated at the point where receiving has been completed and the receive data incorporated into the shift register has been transferred into the receive data buffer and it sets the interrupt factor flag ISRC to "1". When set in this manner, if the corresponding interrupt mask register EISRC is set to "1" and the CPU is set to interrupt enabled status (I flag = "1"), an interrupt will be generated to the CPU.

When the interrupt mask register EISRC has been set to "0" and interrupt has been disabled, no interrupt is generated to the CPU. Even in this case, the interrupt factor flag ISRC is set to "1".

The interrupt factor flag ISRC is reset to "0" by writing "1".

The generation of this interrupt factor allows reading of the received data.

Also, the interrupt factor flag ISRC is set to "1" when a parity error or framing error is generated.

### Error interrupt

This interrupt factor is generated at the point where a parity error, framing error or overrun error is detected during receiving and it sets the interrupt factor flag ISER to "1". When set in this manner, if the corresponding interrupt mask register EISER is set to "1" and the CPU is set to interrupt enabled status (I flag = "1"), an interrupt will be generated to the CPU.

When the interrupt mask register EISER has been set to "0" and interrupt has been disabled, an interrupt is not generated to the CPU. Even in this case, the interrupt factor flag ISER is set to "1".

The interrupt factor flag ISER is reset to "0" by writing "1".

Since all three types of errors result in the same interrupt factor, you should identify the error that has been generated by the error flags PER (parity error), OER (overrun error) and FER (framing error).

4.11.9 I/O memory of serial interface

Table 4.11.9.1 show the serial interface control bits and their addresses.

Table 4.11.9.1 Serial interface control bits

\*1 Initial value at initial reset

\*2 Not set in the circuit

\*3 Constantly "0" when being read

**ESIF: Serial interface enable register (P1 port function selection) (FF70H•D0)**

Sets P10–P13 to the input/output port for the serial interface.

When "1" is written: Serial interface

When "0" is written: I/O port

Reading: Valid

The ESIF is the serial interface enable register and P10–P13 terminals become serial input/output terminals (SIN, SOUT,  $\overline{\text{SCLK}}$ , SRDY) when "1" is written, and they become I/O port terminals when "0" is written.

Also, see Table 4.11.3.2 for the terminal settings according to the transfer modes.

At initial reset, this register is set to "0".

*Note: A hazard may occur from the P12 ( $\overline{\text{SCLK}}$ ) terminal when ESIF is set to "1". Therefore, wait at least 10  $\mu\text{sec}$  after setting ESIF to "1" before starting a serial data transfer.*

**PUL10: SIN pull-up control register (FF45H•D0)****PUL12:  $\overline{\text{SCLK}}$  pull-up control register (FF45H•D2)**

Sets the pull-up of the SIN terminal and the  $\overline{\text{SCLK}}$  terminals (in the slave mode).

When "1" is written: Pull-up ON

When "0" is written: Pull-up OFF

Reading: Valid

Sets the pull-up resistor built into the SIN (P10) and  $\overline{\text{SCLK}}$  (P12) terminals to ON or OFF. (Pull-up resistor is only built in the port selected by mask option.)

$\overline{\text{SCLK}}$  pull-up is effective only in the slave mode. In the master mode, the PUL12 register can be used as a general purpose register.

At initial reset, these registers are set to "1" and the lines are pulled up.

**SMD0, SMD1: Serial interface mode selection register (FF70H•D1, D2)**

Set the transfer modes as shown in Table 4.11.9.2.

Table 4.11.9.2 Transfer mode settings

SMD1	SMD0	Mode
1	1	8-bit asynchronous
1	0	7-bit asynchronous
0	1	Clock synchronous slave
0	0	Clock synchronous master

SMD0 and SMD1 can also read out.

At initial reset, this register is set to "0".

**SCS0, SCS1: Clock source selection register (FF71H•D0, D1)**

Select the clock source as shown in Table 4.11.9.3.

Table 4.11.9.3 Clock source selection

SCS1	SCS0	Clock source
1	1	Programmable timer
1	0	fosc3 / 93
0	1	fosc3 / 372
0	0	fosc3 / 186

SCS0 and SCS1 can also be read out.

In the clock synchronous slave mode, setting of this register is invalid.

At initial reset, this register is set to "0".

**EPR: Parity enable register (FF71H•D3)**

Selects the parity function.

- When "1" is written: With parity
- When "0" is written: Non parity
- Reading: Valid

Selects whether or not to check parity of the received data and to add a parity bit to the transmitting data. When "1" is written to EPR, the most significant bit of the received data is considered to be the parity bit and a parity check is executed. A parity bit is added to the transmitting data. When "0" is written, neither checking is done nor is a parity bit added.

Parity is valid only in asynchronous mode and the EPR setting becomes invalid in the clock synchronous mode.

At initial reset, this register is set to "0".

**PMD: Parity mode selection register (FF71H•D2)**

Selects odd parity/even parity.

- When "1" is written: Odd parity
- When "0" is written: Even parity
- Reading: Valid

When "1" is written to PMD, odd parity is selected and even parity is selected when "0" is written. The parity check and addition of a parity bit is only valid when "1" has been written to EPR. When "0" has been written to EPR, the parity setting by PMD becomes invalid.

At initial reset, this register is set to "0".

**TXEN: Transmit enable register (FF72H•D0)**

Sets the serial interface to the transmit enabled status.

- When "1" is written: Transmit enabled
- When "0" is written: Transmit disabled
- Reading: Valid

When "1" is written to TXEN, the serial interface shifts to the transmit enabled status and shifts to the transmit disabled status when "0" is written.

Set TXEN to "0" when making the initial settings of the serial interface and similar operations.

At initial reset, this register is set to "0".

**TXTRG: Transmit trigger/status (FF72H•D1)**

Functions as the transmit start trigger and the operation status indicator (transmitting/stop status).

- When "1" is read: During transmitting
- When "0" is read: During stop
- When "1" is written: Start transmitting
- When "0" is written: Invalid

Starts transmitting when "1" is written to TXTRG after writing the transmitting data.

TXTRG can be read as the status. When set to "1", it indicates transmitting operation, and "0" indicates transmitting stop.

At initial reset, TXTRG is set to "0".

**RXEN: Receive enable register (FF72H•D2)**

Sets the serial interface to the receive enabled status.

When "1" is written: Receive enabled

When "0" is written: Receive disabled

Reading: Valid

When "1" is written to RXEN, the serial interface shifts to the receive enabled status and shifts to the receive disabled status when "0" is written.

Set RXEN to "0" when making the initial settings of the serial interface and similar operations.

At initial reset, this register is set to "0".

**RXTRG: Receive trigger/status (FF72H•D3)**

Functions as the receive start trigger or preparation for the following data receiving and the operation status indicator (during receiving/during stop).

When "1" is read: During receiving

When "0" is read: During stop

When "1" is written: Start receiving/ following data receiving preparation

When "0" is written: Invalid

RXTRG has a slightly different operation in the clock synchronous system and the asynchronous system.

The RXTRG in the clock synchronous system is used as the trigger for starting receive operation.

Write "1" into RXTRG to start receiving at the point where the receive data has been read and the following receive preparation has been done. (In the slave mode,  $\overline{\text{SRDY}}$  becomes "0" at the point where "1" has been written into the RXTRG.)

In the asynchronous system, RXTRG is used for preparation of the following data receiving. Read the received data located in the receive data buffer and write "1" into RXTRG to inform that the receive data buffer has shifted to empty. When "1" has not been written to RXTRG, the overrun error flag OER is set to "1" at the point where the following receiving has been completed. (When the receiving has been completed between the operation to read the received data and the operation to write "1" into RXTRG, an overrun error occurs.)

In addition, RXTRG can be read as the status. In either clock synchronous mode or asynchronous mode, when RXTRG is set to "1", it indicates receiving operation and when set to "0", it indicates that receiving has stopped.

At initial reset, RXTRG is set to "0".

**TRXD0–TRXD7: Transmit/receive data (FF74H, FF75H)**

*During transmitting*

Transmitting data is set.

When "1" is written: High level

When "0" is written: Low level

Write the transmitting data prior to starting transmission.

In the case of continuous transmitting, wait for the transmit completion interrupt, then write the data.

The TRXD7 becomes invalid for the 7-bit asynchronous mode.

Converted serial data for which the bits set at "1" as High (VDD) level and for which the bits set at "0" as Low (VSS) level are output from the SOUT terminal.

*During receiving*

The received data is stored.

When "1" is read: High level

When "0" is read: Low level

The data from the receive data buffer can be read out.

Since the shift register is provided separately from this buffer, reading can be done during a receive operation in the asynchronous mode. (The buffer function is not used in the clock synchronous mode.)

Read the data after waiting for a receive completion interrupt.

When performing parity check in the 7-bit asynchronous mode, "0" is loaded into the 8th bit (TRXD7) that corresponds to the parity bit.

The serial data input from the SIN terminal is level converted, making the High (VDD) level bit "1" and the Low (VSS) level bit "0" and is then loaded into this buffer.

At initial reset, the buffer content is undefined.

### **OER: Overrun error flag (FF73H•D0)**

Indicates the generation of an overrun error.

When "1" is read: Error

When "0" is read: No error

When "1" is written: Reset to "0"

When "0" is written: Invalid

OER is an error flag that indicates the generation of an overrun error and becomes "1" when an error has been generated.

An overrun error is generated when a receiving of data has completed prior to writing "1" to RXTRG in the asynchronous mode.

OER is reset to "0" by writing "1".

OER is set to "0" at initial reset or when RXEN is set to "0".

### **PER: Parity error flag (FF73H•D1)**

Indicates the generation of a parity error.

When "1" is read: Error

When "0" is read: No error

When "1" is written: Reset to "0"

When "0" is written: Invalid

PER is an error flag that indicates the generation of a parity error and becomes "1" when an error has been generated.

When a parity check is performed in the asynchronous mode, a parity error will be generated if data that does not match the parity is received.

PER is reset to "0" by writing "1".

PER is set to "0" at initial reset or when RXEN is set to "0".

### **FER: Framing error flag (FF73H•D2)**

Indicates the generation of a framing error.

When "1" is read: Error

When "0" is read: No error

When "1" is written: Reset to "0"

When "0" is written: Invalid

FER is an error flag that indicates the generation of a framing error and becomes "1" when an error has been generated.

When the stop bit for the receiving in the asynchronous mode has become "0", a framing error is generated.

FER is reset to "0" by writing "1".

FER is set to "0" at initial reset or when RXEN is set to "0".

**EISRC, EISTR, EISER: Interrupt mask registers (FFE3H•D0, D1, D2)**

Enables or disables the generation of an interrupt for the CPU.

When "1" is written: Enabled

When "0" is written: Disabled

Reading: Valid

EISRC, EISTR and EISER are interrupt mask registers that respectively correspond to the interrupt factors for receive completion, transmit completion and receive error. Interrupts set to "1" are enabled and interrupts set to "0" are disabled.

At initial reset, these registers are set to "0".

**ISRC, ISTR, ISER: Interrupt factor flags (FFF3H•D0, D1, D2)**

Indicates the serial interface interrupt generation status.

When "1" is read: Interrupt has occurred

When "0" is read: Interrupt has not occurred

When "1" is written: Flag is reset

When "0" is written: Invalid

ISRC, ISTR and ISER are interrupt factor flags that respectively correspond to the interrupts for receive completion, transmit completion and receive error, and are set to "1" by generation of each factor.

Transmit completion interrupt factor is generated at the point where the data transmission of the shift register has been completed.

Receive completion interrupt factor is generated at the point where the received data has been transferred into the receive data buffer.

Receive error interrupt factor is generated when a parity error, framing error or overrun error has been detected during data receiving.

When set in this manner, if the corresponding interrupt enable mask is set to "1" and the CPU is set to interrupt enabled status (I flag = "1"), an interrupt will be generated to the CPU.

Regardless of the interrupt mask register setting, the interrupt factor flag will be set to "1" by the occurrence of an interrupt generation condition.

The interrupt factor flag is reset to "0" by writing "1".

After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.

At initial reset, these flags are set to "0".

**4.11.10 Programming notes**

- (1) Be sure to initialize the serial interface mode in the transmit/receive disabled status (TXEN = RXEN = "0").
- (2) Do not perform double trigger (writing "1") to TXTRG (RXTRG) when the serial interface is in the transmitting (receiving) operation.
- (3) In the clock synchronous mode, since one clock line ( $\overline{SCLK}$ ) is shared for both transmitting and receiving, transmitting and receiving cannot be performed simultaneously. (Half duplex only is possible in clock synchronous mode.)  
Consequently, be sure not to write "1" to RXTRG (TXTRG) when TXTRG (RXTRG) is "1".
- (4) When a parity error or framing error is generated during receiving in the asynchronous mode, the receiving error interrupt factor flag ISER is set to "1" prior to the receive completion interrupt factor flag ISRC for the time indicated in Table 4.11.10.1. Consequently, when an error is generated, you should reset the receiving complete interrupt factor flag ISRC to "0" by providing a wait time in error processing routines and similar routines.  
When an overrun error is generated, the receiving complete interrupt factor flag ISRC is not set to "1" and a receiving complete interrupt is not generated.

*Table 4.11.10.1 Time difference between ISER and ISRC on error generation*

Clock source	Time difference
fosc3 / n	1/2 cycles of fosc3 / n
Programmable timer	1 cycle of timer 1 underflow

- (5) When the demultiplied signal of the OSC3 oscillation circuit is made the clock source, it is necessary to turn the OSC3 oscillation ON, prior to using the serial interface.  
A time interval of 5 msec, from the turning ON of the OSC3 oscillation circuit to until the oscillation stabilizes, is necessary, due to the oscillation element that is used. Consequently, you should allow an adequate waiting time after turning ON of the OSC3 oscillation, before starting transmitting/receiving of serial interface. (The oscillation start time will vary somewhat depending on the oscillator and on the externally attached parts. Refer to the oscillation start time example indicated in Chapter 7, "Electrical Characteristics".)  
At initial reset, the OSC3 oscillation circuit is set to OFF status.
- (6) Be aware that the maximum clock frequency for the serial interface is limited to 1 MHz.
- (7) After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.

## 4.12 Sound Generator

### 4.12.1 Configuration of sound generator

The E0C63567 has a built-in sound generator for generating buzzer signals. Hence, generated buzzer signals can be output from the R00 (XBZ) and R01 (BZ) terminals. Aside permitting the respective setting of the buzzer signal frequency and sound level to 8 stages, it permits the adding of a digital envelope by means of duty ratio control. It also has a one-shot output function for outputting key operated sounds. Figure 4.12.1.1 shows the configuration of the sound generator.

Fig. 4.12.1.1 Configuration of sound generator

*Note:* The buzzer signal is generated by dividing the OSC1 oscillation clock. Since the frequencies and times that are described in this section are the values in the case of crystal oscillation (32.768 kHz, Typ.), they differ when CR oscillation (60 kHz, Typ.) is selected.

### 4.12.2 Buzzer output circuit

The E0C63567 uses the R01 (BZ) and R00 (XBZ) terminals for outputting buzzer signals. To drive a piezoelectric buzzer with one terminal, use the BZ signal output from the R01 (BZ) terminal. The piezoelectric buzzer should be driven via a bipolar transistor. Since the R01 (BZ) terminal goes High level when the buzzer signal is stopped, use a PNP transistor as shown in Figure 4.12.2.1.

Fig. 4.12.2.1 Buzzer output circuit using the R01 (BZ) terminal

The E0C63567 allows direct driving of a piezoelectric buzzer using both the R01 (BZ) and R00 (XBZ) terminals. In this case, a piezoelectric buzzer should be connected to these terminals via protection resistors (100 Ω) as shown in Figure 4.12.2.2.

Fig. 4.12.2.2 Direct driving a piezoelectric buzzer using the R01 (BZ) and R00 (XBZ) terminals

### 4.12.3 Control of buzzer output

The R01 and R00 terminals for buzzer output are set as general-purpose output ports at initial reset. Therefore, the R01 terminal must be set as the BZ output terminal by writing "1" to the BZOUT register before controlling buzzer output. Furthermore, the data register R01 for the R01 output port should be fixed at "1" and the high-impedance register R01HIZ at "0".

When direct driving a piezoelectric buzzer, the R00 terminal must be set as the XBZ output terminal similar to the R01 terminal. Write "1" to the XBZOUT register to set the XBZ output. Also in this case, the data register R00 for the R00 output port should be fixed at "1" and the high-impedance register R00HIZ at "0".

The buzzer signals generated by the sound generator are output from the BZ (R01) and XBZ (R00) terminals by writing "1" to the buzzer output enable register BZE. When "0" is written to the BZE register, the BZ (R01) terminal goes High (VDD) and XBZ (R00) terminal goes Low (Vss).

Fig. 4.12.3.1 Buzzer signal output timing chart

*Note:* Since the BZ and XBZ signals are generated asynchronous to the BZE register, hazards may be produced when the signal goes ON/OFF due to the setting of the BZE register.

#### 4.12.4 Setting of buzzer frequency and sound level

The divided signal of the OSC1 oscillation clock (32.768 kHz) is used for the buzzer (BZ, XBZ) signals and it is set up such that 8 types of frequencies can be selected by changing this division ratio. Frequency selection is done by setting the buzzer frequency selection registers BZFQ0–BZFQ2 as shown in Table 4.12.4.1.

Table 4.12.4.1 Buzzer signal frequency setting

BZFQ2	BZFQ1	BZFQ0	Buzzer frequency (Hz)
0	0	0	4096.0
0	0	1	3276.8
0	1	0	2730.7
0	1	1	2340.6
1	0	0	2048.0
1	0	1	1638.4
1	1	0	1365.3
1	1	1	1170.3

The buzzer sound level is changed by controlling the duty ratio of the buzzer signal.

The duty ratio can be selected from among the 8 types shown in Table 4.12.4.2 according to the setting of the buzzer duty selection registers BDTY0–BDTY2.

Table 4.12.4.2 Duty ratio setting

Level	BDTY2	BDTY1	BDTY0	Duty ratio by buzzer frequency (Hz)			
				4096.0	3276.8	2730.7	2340.6
				2048.0	1638.4	1365.3	1170.3
Level 1 (Max.)	0	0	0	8/16	8/20	12/24	12/28
Level 2	0	0	1	7/16	7/20	11/24	11/28
Level 3	0	1	0	6/16	6/20	10/24	10/28
Level 4	0	1	1	5/16	5/20	9/24	9/28
Level 5	1	0	0	4/16	4/20	8/24	8/28
Level 6	1	0	1	3/16	3/20	7/24	7/28
Level 7	1	1	0	2/16	2/20	6/24	6/28
Level 8 (Min.)	1	1	1	1/16	1/20	5/24	5/28

When the HIGH level output time has been made TH and when the LOW level output time has been made TL due to the ratio of the pulse width to the pulse synchronization, the duty ratio becomes  $TL/(TH+TL)$  for negative polarity or  $TH/(TH+TL)$  for positive polarity.

When BDTY0–BDTY2 have all been set to "0", the duty ratio becomes maximum and the sound level also becomes maximum. Conversely, when BDTY0–BDTY2 have all been set to "1", the duty ratio becomes minimum and the sound level also becomes minimum.

The duty ratio that can be set is different depending on the frequency that has been set, so see Table 4.12.4.2.

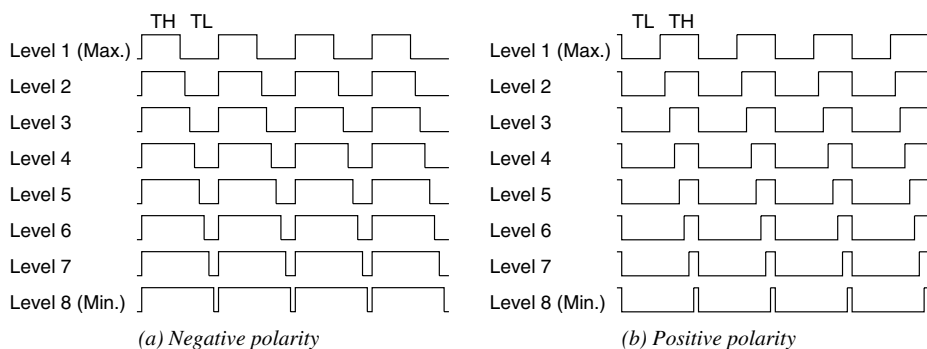

Fig. 4.12.4.1 Duty ratio of the buzzer signal waveform

Note: When a digital envelope has been added to the buzzer signal, the BDTY0–BDTY2 settings will be invalid due to the control of the duty ratio.

### 4.12.5 Digital envelope

A digital envelope for duty control can be added to the buzzer signal.

The envelope can be controlled by staged changing of the same duty envelope as detailed in Table 4.12.4.2 in the preceding item from level 1 (maximum) to level 8 (minimum).

The addition of an envelope to the buzzer signal can be done by writing "1" into ENON, but when "0" has been written it is not added.

When a buzzer signal output is begun (writing "1" into BZE) after setting ENON, the duty ratio shifts to level 1 (maximum) and changes in stages to level 8.

When attenuated down to level 8 (minimum), it is retained at that level. The duty ratio can be returned to maximum, by writing "1" into register ENRST during output of a envelope attached buzzer signal.

The envelope attenuation time (time for changing of the duty ratio) can be selected by the register ENRTM. The time for a 1 stage level change is 62.5 msec (16 Hz), when "0" has been written into ENRTM and 125 msec (8 Hz), when to "1" has been written. However, there is also a max. 4 msec error from envelope ON, up to the first change.

Figure 4.12.5.1 shows the timing chart of the digital envelope.

Fig. 4.12.5.1 Timing chart for digital envelope

### 4.12.6 One-shot output

The sound generator has a one-shot output function for outputting a short duration buzzer signal for key operation sounds and similar effects. Either 125 msec or 31.25 msec can be selected by SHTPW register for one-shot buzzer signal output time.

The output of the one-shot buzzer is controlled by writing "1" into the one-shot buzzer trigger BZSHT. When this trigger has been assigned, a buzzer signal in synchronization with the internal 256 Hz signal is output from the BZ and XBZ terminals. Thereafter, when the set time has elapsed, a buzzer signal in synchronization with the 256 Hz signal goes off in the same manner as for the start of output. The BZSHT also permits reading. When BZSHT is "1", the one-shot output circuit is in operation (during one-shot output) and when it is "0", it shows that the circuit is in the ready (outputtable) status.

In addition, it can also terminate one-shot output prior to the elapsing of the set time. This is done by writing a "1" into the one-shot buzzer stop BZSTP. In this case as well, the buzzer signal goes OFF in synchronization with the 256 Hz signal.

When "1" is written to BZSHT again during a one-shot output, a new one-shot output for 125 msec or 31.25 msec starts from that point (in synchronization with the 256 Hz signal).

The one-shot output cannot add an envelope for short durations. However, the sound level can be set by selecting the duty ratio, and the frequency can also be set.

One-shot output is invalid during normal buzzer output (during BZE = "1").

Figure 4.12.6.1 shows timing chart for one-shot output.

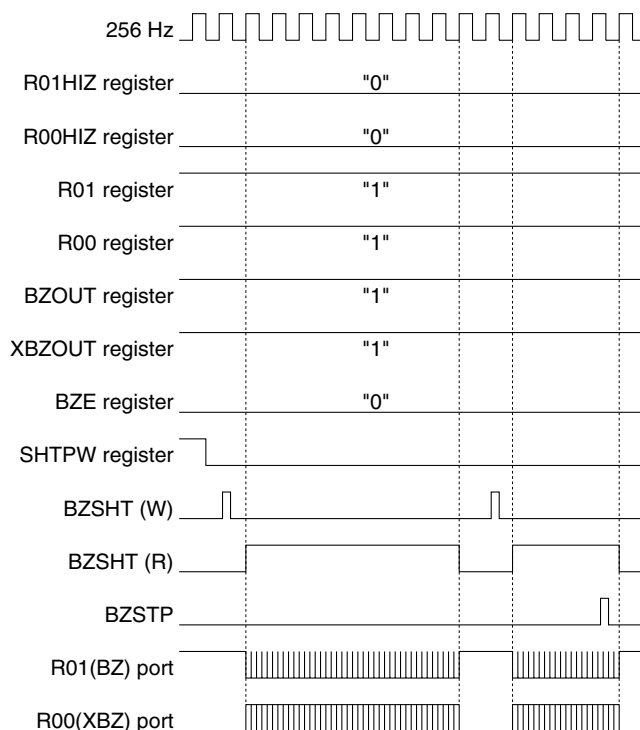

Fig. 4.12.6.1 Timing chart for one-shot output

4.12.7 I/O memory of sound generator

Table 4.12.7.1 shows the I/O addresses and the control bits for the sound generator.

\*1 Initial value at initial reset

\*2 Not set in the circuit

\*3 Constantly "0" when being read

**R00HIZ, R01HIZ: R00, R01 port high impedance control register (FF30H•D0, D1)**

Controls high impedance output of the output port.

When "1" is written: High impedance

When "0" is written: Data output

Reading: Valid

When using the BZ and XBZ outputs, fix the registers at "0". R01HIZ corresponds to the BZ output and R00HIZ corresponds to the XBZ output.

At initial reset, these registers are set to "0".

**R00, R01: R00, R01 output port data register (FF31H• D0, D1)**

Set the output data for the output ports.

When "1" is written: High level output

When "0" is written: Low level output

Reading: Valid

When using the BZ and XBZ outputs, fix the registers at "1". R01 corresponds to the BZ output and R00 corresponds to the XBZ output.

At initial reset, these registers are all set to "1".

**XBZOUT: R00 output selection register (FF65H•D0)**

Selects the R00 terminal function.

- When "1" is written: XBZ output
- When "0" is written: General-purpose DC output
- Reading: Valid

When using the R00 terminal for the XBZ output, write "1" to this register. Furthermore, fix the R00 register at "1" and the R00HIZ register at "0".

At initial reset, this register is set to "0".

**BZOUT: R01 output selection register (FF65H•D1)**

Selects the R01 terminal function.

- When "1" is written: BZ output
- When "0" is written: General-purpose DC output
- Reading: Valid

When using the R01 terminal for the BZ output, write "1" to this register. Furthermore, fix the R01 register at "1" and the R01HIZ register at "0".

At initial reset, this register is set to "0".

**BZE: BZ output control register (FF6CH•D0)**

Controls the buzzer signal output.

- When "1" is written: Buzzer output ON
- When "0" is written: Buzzer output OFF
- Reading: Valid

When "1" is written to BZE, the BZ signal is output from the BZ (R01) terminal and the XBZ signal is output from the XBZ (R00) terminal.

When "0" is written, the buzzer signals go OFF.

At initial reset, this register is set to "0".

**BZFQ0–BZFQ2: Buzzer frequency selection register (FF6EH•D0–D2)**

Selects the buzzer signal frequency.

*Table 4.12.7.2 Buzzer signal frequency setting*

BZFQ2	BZFQ1	BZFQ0	Buzzer frequency (Hz)
0	0	0	4096.0
0	0	1	3276.8
0	1	0	2730.7
0	1	1	2340.6
1	0	0	2048.0
1	0	1	1638.4
1	1	0	1365.3
1	1	1	1170.3

Select the buzzer frequency from among the above 8 types that have divided the oscillation clock.

At initial reset, this register is set to "0".

**BDTY0–BDTY2: Duty level selection register (FF6FH•D0–D2)**

Selects the duty ratio of the buzzer signal as shown in Table 4.12.7.3.

Table 4.12.7.3 Duty ratio setting

Level	BDTY2	BDTY1	BDTY0	Duty ratio by buzzer frequency (Hz)			
				4096.0 2048.0	3276.8 1638.4	2730.7 1365.3	2340.6 1170.3
Level 1 (Max.)	0	0	0	8/16	8/20	12/24	12/28
Level 2	0	0	1	7/16	7/20	11/24	11/28
Level 3	0	1	0	6/16	6/20	10/24	10/28
Level 4	0	1	1	5/16	5/20	9/24	9/28
Level 5	1	0	0	4/16	4/20	8/24	8/28
Level 6	1	0	1	3/16	3/20	7/24	7/28
Level 7	1	1	0	2/16	2/20	6/24	6/28
Level 8 (Min.)	1	1	1	1/16	1/20	5/24	5/28

The sound level of this buzzer can be set by selecting this duty ratio. However, when the envelope has been set to ON (ENON = "1"), this setting becomes invalid. At initial reset, this register is set to "0".

**ENRST: Envelope reset (FF6CH•D2)**

Resets the envelope.

- When "1" is written: Reset
- When "0" is written: No operation
- Reading: Always "0"

Writing "1" into ENRST resets envelope and the duty ratio becomes maximum. If an envelope has not been added (ENON = "0") and if no buzzer signal is being output, the reset becomes invalid. Writing "0" is also invalid.

This bit is dedicated for writing, and is always "0" for reading.

**ENON: Envelope ON/OFF control register (FF6CH•D1)**

Controls the addition of an envelope onto the buzzer signal.

- When "1" is written: ON
- When "0" is written: OFF
- Reading: Valid

Writing "1" into the ENON causes an envelope to be added during buzzer signal output. When a "0" has been written, an envelope is not added.

At initial reset, this register is set to "0".

**ENRTM: Envelope releasing time selection register (FF6CH•D3)**

Selects the envelope releasing time that is added to the buzzer signal.

- When "1" is written: 1.0 sec (125 msec × 7 = 875 msec)
- When "0" is written: 0.5 sec (62.5 msec × 7 = 437.5 msec)
- Reading: Valid

The releasing time of the digital envelope is determined by the time for converting the duty ratio.

When "1" has been written in ENRTM, it becomes 125 msec (8 Hz) units and when "0" has been written, it becomes 62.5 msec (16 Hz) units.

At initial reset, this register is set to "0".

**SHTPW: One-shot buzzer pulse width setting register (FF6DH•D0)**

Selects the output time of the one-shot buzzer.

When "1" is written: 125 msec

When "0" is written: 31.25 msec

Reading: Valid

Writing "1" into SHTPW causes the one-short output time to be set at 125 msec, and writing "0" causes it to be set to 31.25 msec. It does not affect normal buzzer output.

At initial reset, this register is set to "0".

**BZSHT: One-shot buzzer trigger/status (FF6DH•D1)**

Controls the one-shot buzzer output.

**•When writing**

When "1" is written: Trigger

When "0" is written: No operation

Writing "1" into BZSHT causes the one-short output circuit to operate and a buzzer signal to be output. This output is automatically turned OFF after the time set by SHTPW has elapsed. The one-shot output is only valid when the normal buzzer output is OFF (BZE = "0") and will be invalid when the normal buzzer output is ON (BZE = "1"). When a re-trigger is assigned during a one-shot output, the one-shot output time set with SHTPW is measured again from that point (time extension).

**•When reading**

When "1" is read: BUSY

When "0" is read: READY

During reading BZSHT shows the operation status of the one-shot output circuit. During one-shot output, BZSHT becomes "1" and the output goes OFF, it shifts to "0".

At initial reset, this bit is set to "0".

**BZSTP: One-shot buzzer stop (FF6DH•D2)**

Stops the one-shot buzzer output.

When "1" is written: Stop

When "0" is written: No operation

Reading: Always "0"

Writing "1" into BZSTP permits the one-shot buzzer output to be turned OFF prior to the elapsing of the time set by SHTPW. Writing "0" is invalid and writing "1" is also invalid except during one-shot output. This bit is dedicated for writing, and is always "0" for reading.

**4.12.8 Programming notes**

- (1) Since the BZ and XBZ signals are generated asynchronous to the BZE register, hazards may be produced when the signal goes ON/OFF due to the setting of the BZE register.
- (2) The one-shot output is only valid when the normal buzzer output is OFF (BZE = "0") and will be invalid when the normal buzzer output is ON (BZE = "1").
- (3) Since the BZ and XBZ signals are the special outputs of the R01 and R00 ports, it is necessary to set the high impedance control registers (R01HIZ, R00HIZ) to "0", the data registers (R01, R00) to "1" and the output selection registers (BZOUT, XBZOUT) to "1" before setting the BZE register to "1".
- (4) The buzzer signal is generated by dividing the OSC1 oscillation clock. Since the frequencies and times that are described in this section are the values in the case of crystal oscillation (32.768 kHz, Typ.), they differ when CR oscillation (60 kHz, Typ.) is selected.

### 4.13 SVD (Supply Voltage Detection) Circuit

#### 4.13.1 Configuration of SVD circuit

The E0C63567 has a built-in SVD (supply voltage detection) circuit, so that the software can find when the source voltage lowers. It is possible to check an external voltage drop, other than the supply voltage, by mask option.

Turning the SVD circuit ON/OFF and the SVD criteria voltage setting can be done with software.

Figure 4.13.1.1 shows the configuration of the SVD circuit.

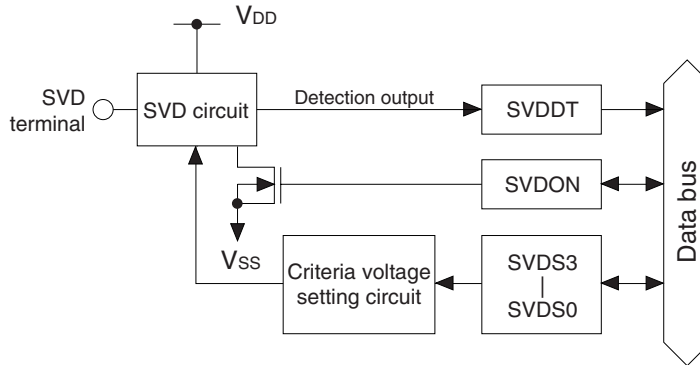

Fig. 4.13.1.1 Configuration of SVD circuit

#### 4.13.2 Mask option

Besides the supply voltage (VDD terminal–VSS terminal) drop detection, the SVD circuit can detect the external voltage (SVD terminal–VSS terminal) input from the SVD terminal by comparing it with the detected voltage (0.95 V). This function can select whether or not to use with the mask option.

#### 4.13.3 SVD operation

The SVD circuit compares the criteria voltage set by software and the supply voltage (VDD terminal–VSS terminal) or the external voltage (SVD terminal–VSS terminal) and sets its results into the SVDDT latch. By reading the data of this SVDDT latch, it can be determined by means of software whether the supply voltage is normal or has dropped.

The criteria voltage can be set for the 12 types shown in Table 4.13.3.1 by the SVDS3–SVDS0 registers. When "0" is written to the SVDS3–SVDS0 register, the supply voltage detection voltage is set to 2.20 V. However, when "External voltage detection" is selected by mask option, the SVD circuit does not compare the supply voltage (VDD terminal–VSS terminal) but compares between the external voltage (SVD terminal–VSS terminal) input from the SVD terminal and 0.95 V.

Table 4.13.3.1 Criteria voltage setting

SVDS3	SVDS2	SVDS1	SVDS0	Criteria voltage (V)	SVDS3	SVDS2	SVDS1	SVDS0	Criteria voltage (V)
0	1	1	1	2.50	1	1	1	1	3.30
0	1	1	0	2.40	1	1	1	0	3.20
0	1	0	1	2.30	1	1	0	1	3.10
0	1	0	0	2.20	1	1	0	0	3.00
0	0	1	1	2.20	1	0	1	1	2.90
0	0	1	0	2.20	1	0	1	0	2.80
0	0	0	1	2.20	1	0	0	1	2.70
0	0	0	0	2.20/0.95	1	0	0	0	2.60

When the SVDON register is set to "1", source voltage or external voltage detection by the SVD circuit is executed. As soon as the SVDON register is reset to "0", the result is loaded to the SVDDT latch and the SVD circuit goes OFF.

To obtain a stable detection result, the SVD circuit must be ON for at least 100 µsec. So, to obtain the SVD detection result, follow the programming sequence below.

1. Set SVDON to "1"
2. Maintain for 100 µsec minimum
3. Set SVDON to "0"
4. Read SVDDT

When the SVD circuit is ON, the IC draws a large current, so keep the SVD circuit off unless it is.

#### 4.13.4 I/O memory of SVD circuit

Table 4.13.4.1 shows the I/O addresses and the control bits for the SVD circuit.

Table 4.13.4.1 Control bits of SVD circuit

Address	Register				Name	Init *1	1	0	Comment
	D3	D2	D1	D0					
FF04H	SVDS3	SVDS2	SVDS1	SVDS0	SVDS3	0			SVD criteria voltage setting [SVDS3-0] 0 1 2 3 4 5 6 7 Voltage(V) 2.20/0.95 2.20 2.20 2.20 2.20 2.30 2.40 2.50 [SVDS3-0] 8 9 10 11 12 13 14 15 Voltage(V) 2.60 2.70 2.80 2.90 3.00 3.10 3.20 3.30
	R/W				SVDS2	0			
					SVDS1	0			
					SVDS0	0			
FF05H	0	0	SVDDT	SVDON	0 *3	- *2			Unused
	R				0 *3	- *2			Unused
				R/W	SVDDT	0	Low	Normal	SVD evaluation data
					SVDON	0	On	Off	SVD circuit On/Off

\*1 Initial value at initial reset

\*2 Not set in the circuit

\*3 Constantly "0" when being read

#### SVDS3–SVDS0: SVD criteria voltage setting register (FF04H)

Criteria voltage for SVD is set as shown in Table 4.13.3.1.

At initial reset, this register is set to "0".

#### SVDON: SVD control (ON/OFF) register (FF05H•D0)

Turns the SVD circuit ON and OFF.

When "1" is written: SVD circuit ON

When "0" is written: SVD circuit OFF

Reading: Valid

When the SVDON register is set to "1", a source voltage detection is executed by the SVD circuit. As soon as SVDON is reset to "0", the result is loaded to the SVDDT latch. To obtain a stable detection result, the SVD circuit must be ON for at least 100 µsec.

At initial reset, this register is set to "0".

#### SVDDT: SVD data (FF05H•D1)

This is the result of supply voltage detection.

When "0" is read: Supply voltage (VDD–Vss) ≥ Criteria voltage

When "1" is read: Supply voltage (VDD–Vss) < Criteria voltage

Writing: Invalid

The result of supply voltage detection at time of SVDON is set to "0" can be read from this latch.

At initial reset, SVDDT is set to "0".

### ***4.13.5 Programming notes***

- (1) To obtain a stable detection result, the SVD circuit must be ON for at least 100  $\mu$ sec. So, to obtain the SVD detection result, follow the programming sequence below.
  1. Set SVDON to "1"
  2. Maintain for 100  $\mu$ sec minimum
  3. Set SVDON to "0"
  4. Read SVDDT
- (2) The SVD circuit should normally be turned OFF because SVD operation increase current consumption.

## 4.14 Telephone Function (Tone/Pulse Dialer)

### 4.14.1 Configuration of tone/pulse dialer

The E0C63567 has a telephone function built-in. This function includes DTMF (Dual Tone Multi-Frequency), DP (Dialing pulse), Pause, Flash, Hold-line, Mute control, Hook switch control and Handfree control.

The configuration of the telephone function is shown in Figure 4.14.1.1.

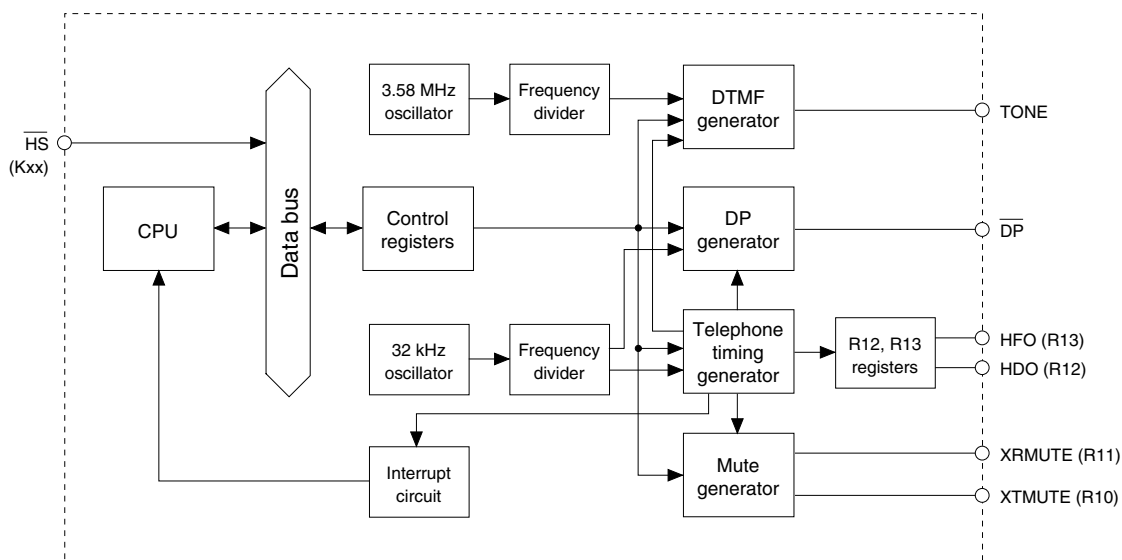

Fig. 4.14.1.1 Configuration of tone/pulse dialer

This dialer has built-in a DTMF generator for generating tones and a DP generator for generating dial pulses.

Either DTMF mode or DP mode can be selected by software.

In the DTMF mode, the DTMF generator uses the OSC3 (3.58 MHz) clock to generate the tone signal set by software (signal tone or dual tone) and outputs it to the TONE terminal.

In the DP mode, the DP generator uses the OSC1 (32 kHz) clock to generate the dial pulses for the number set by software to the  $\overline{DP}$  terminal.

The push button matrix is configured using the input and output ports. The hook switch should be connected to an input port. The hook switch can be controlled by software, this makes it possible to start calling even if the telephone is on-hook.

Besides the above terminals, The R10 to R13 terminals can be used as an XTMUTE (transmitter mute signal output), XRMUTE (receiver mute signal output), HDO (hold line signal output) and HFO (hand free signal output). These terminal functions can be configured by software. (See Section 4.5, "Output Ports".)

This dialer has a built-in interrupt circuit that can generate an interrupt when execution of a dial signal output, a pause function or a flash function is completed.

### 4.14.2 Mask option

Output specifications for the  $\overline{DP}$  terminal is selected from between complementary output and Nch open drain output by mask option.

Since the R10 to R13 terminals are used for XTMUTE, XRMUTE, HDO and HFO outputs, the output specifications of the output ports R10–R13 apply to their output specifications. Either complementary output or Nch open drain output can be selected for each terminal by the output port mask option.

However, even when Nch open drain output is selected, voltage exceeding source voltage must not be applied to the output terminals.

Mask option allows use of the DTS (tone duration time selection) function. If DTS is used, the tone duration time can be set to 47 msec or 94 msec using the DTS (FF16H•D2) register. If not, the register is always set to "0". So the tone duration time is fixed at 94 msec.

### 4.14.3 Operation of telephone function

To realize the operation of the telephone function, dialing procedure is the most important concept. This procedure contains three steps: (1) setting, (2) executing and (3) interrupt.

#### (1) Setting

Every function has its control registers. It is necessary to set the appropriate control registers before execution. Table 4.14.3.1 lists the relations of functions and control registers.

Table 4.14.3.1 Control registers and default setting

Functions	Control registers	Initial setting
DTMF	TPS (FF10H•D3)	Tone mode
	SINC, SINR (FF16H)	Dual tone
	DTS (FF16H•D2)	Tone duration selection
DP	TPS (FF10H•D3)	Tone mode
	MB (FF10H•D1)	40 : 60
	DRS (FF10H•D0)	10 pps
	IDP3–IDP0 (FF15H)	750 ms
PAUSE	PTS3–PTS0 (FF11H)	4 sec
FLASH	FTS3–FTS0 (FF12H)	563 ms

See Section 4.14.10, "I/O memory of telephone function", for details of each control register.

#### Operating mode

This dialer has built-in a DTMF generator for generating tones and a DP generator for generating dial pulses. Two basic operating modes are provided: tone mode and pulse mode. The mode can be switched by software (TPS register). This setting must be performed prior to the dial processing. At initial reset, tone mode is set.

The following operating condition should be set according to the operating mode:

- Tone mode:
  - Selecting single tone or dual tone output
  - Selecting minimum tone duration time (depending on mask option selection)
- Pulse mode:
  - Setting a make ratio (40:60 or 33.3:66.6)
  - Setting a pulse rate (10 pps or 20 pps)
  - Setting an inter digit pause time (94 msec to 1,406 msec; selected from among 15 types)

Details will be discussed later.

The tone mode uses the OSC3 (3.58 MHz) clock, so the OSC3 oscillation must be turned ON (OSCC = "1") prior to dialing. However, it is not necessary to switch the CPU system clock to OSC3.

When executing the pause or flash function, the period of time should be set.

Pause time: 1 to 15 sec (1-sec units; selected from among 15 types)

Flash time: 94 msec to 1,406 msec (selected from among 15 types)

Furthermore, to use the R10 to R13 terminals for the XTMUTE, XRMUTE, HDO and HFO outputs, the output port functions must be switched to the dialer using the CTMO, CRMO, CHDO and CHFO registers (by writing "1"). This switching should be followed the procedure shown in Figure 4.14.3.1 (sample XTMUTE and XRMUTE outputs). The high impedance control registers (R10HIZ–R13HIZ) must be fixed at "0" and the data registers (R10–R13) at "1" before writing "1" to the CTMO, CRMO, CHDO and CHFO registers. Also the mute control registers (CTMUT, CRMUT) should be set to "1".

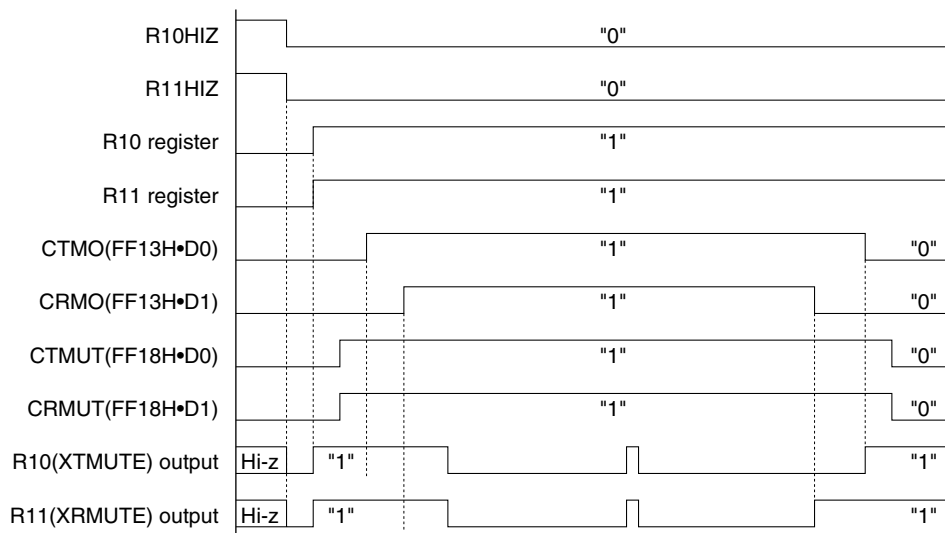

Fig. 4.14.3.1 Output terminal setting procedure

## (2) Executing

After setting, write the corresponding control register to start the execution.

Table 4.14.3.2 lists control registers for executing.

Table 4.14.3.2 Control registers and executing function

Functions	Control registers	Executing function
DTMF	TCD3–TCD0 (FF17H)	Dialing tone
	CTO (FF16H•D3)	Continuous tone output ON/OFF
	HSON (FF18H•D3)	Hook switch ON/OFF
DP	TCD3–TCD0 (FF17H)	Dialing pulse
	HSON (FF18H•D3)	Hook switch ON/OFF
Pause	PAUSE (FF14H•D1)	Pause
Flash	FLASH (FF14H•D0)	Flash
Hold-line	HOLD (FF14H•D2)	Hold-line
Handfree	HF (FF14H•D3)	Handfree

See Section 4.14.10, "I/O memory of telephone function", for details of each control register.

The hook switch (HSON), continuous tone output (CTO), hold-line (HOLD) and handfree (HF) functions and their timings are controlled by software. These functions do not generate interrupts.

The HSON that controls the hook switch must be turned ON (off-hook) before executing the telephone function. Actual handset operations are not taken into the dialer. The HSON register allows on-hook dialing. The hook switch should be connected to an input port (Kxx) and get the switch status using an input interrupt.

By setting data for the dial number (1 digit) to the TCD register after setting HSON to off-hook, the dialer output the dialing tone or dialing pulses according to the condition set in (1). When the output is completed, an interrupt occurs. Use the interrupt for setting the next digit number.

The pause and flash functions are executed by writing "1" to the PAUSE and FLASH bits and will generate an interrupt after the period of time set in (1) has passed. It is not necessary to turn the function OFF.

**(3) Interrupt**

The dialing, pause and flash functions generate an interrupt when their operation has finished. At this time, the interrupt factor flag ID (FFF9H•D0) is set to "1". An interrupt request to the CPU will be generated when the interrupt mask register EID (FFE9H•D0) is set to "1" and will be masked when EID is set to "0". However, the interrupt factor flag ID will be set to "1" when the above function has completed even if the interrupt is masked. The end of operations can also be checked by scanning the ID flag. The ID flag is reset to "0" by writing "1". The ID flag must be cleared to "0" before starting the next interrupt.

Figure 4.14.3.2 shows an example of dialing pulse transmission procedure.

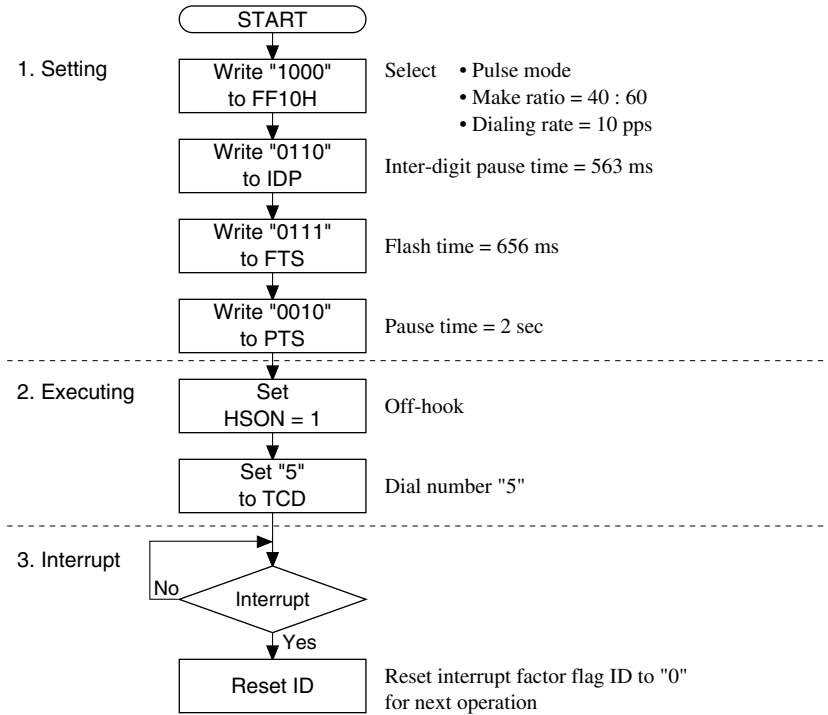

Fig. 4.14.3.2 Flow chart of dialing pulse transmission

In the setting step, "1000B" is written to address FF10H to set pulse (DP) mode, the make ratio = 40:60 and the dialing rate = 10 pps. Then data is written to IDP (FF15H), PTS (FF11H) and FTS (FF12H) to set an inter-digit pause time, pause time and flash time. These settings are not necessary when using the initial set values of IDP, PTS and FTS.

In the executing step, "1" is written to HSON (FF18H•D3) to set off-hook. This makes the  $\overline{DP}$  terminal go to a High (V<sub>DD</sub>) level and connects the telephone line. Then "0101B" (dialling number = 5) is written to TCD (FF17H) to start the dialing operation. The  $\overline{DP}$  terminal outputs 5 pulses according to the condition set. At the same time, the XTMUTE and XRMUTE signals become active (if the R10 and R11 terminals have been set as those signal output ports). In the actual application, this step should include the processing for fetching the hook switch status and for push button inputs.

When a series of pulses has been transmitted, an interrupt occurs. The next digit process can be started after resetting (writing "1" to) the interrupt factor flag ID.

#### 4.14.4 Tone mode (DTMF)

In tone mode, the dialer outputs a tone (pushbutton dial) signal. This mode is set by default at initial reset. To change the mode from pulse mode to this mode, write "0" to the TPS register (FF10H•D3). The PB (tone) signal generates two different frequencies that are determined by the pushed button in the push button matrix as shown in Table 4.14.4.1.

Table 4.14.4.1 PB frequency combination

Frequency (Hz)	COL1 1209	COL2 1336	COL3 1477	COL4 1633
ROW1 697	1	2	3	Unused
ROW2 770	4	5	6	Unused
ROW3 852	7	8	9	Unused
ROW4 941	*	0	#	Unused

The row and column frequencies and the compound tone signal are generated by the DTMF (Dual Tone Multi-Frequency) generator. Figure 4.14.4.1 shows the block diagram of the DTMF generator.

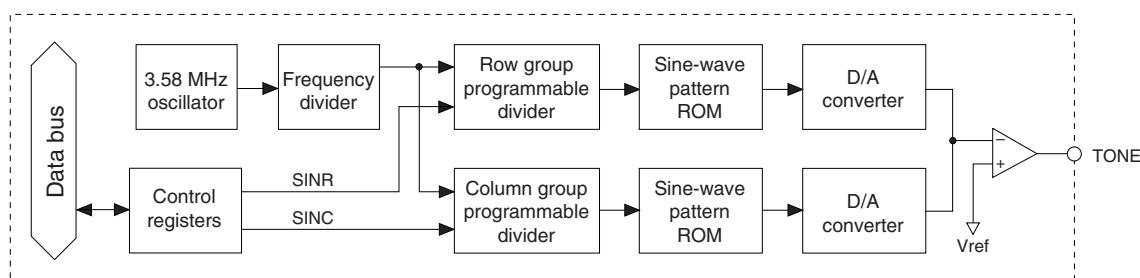

Fig. 4.14.4.1 DTMF generator block diagram

As shown in Figure 4.14.4.1, the DTMF generator generates each frequency by dividing the OSC3 (3.58 MHz) clock. Therefore, the OSC3 oscillation circuit must be turned ON before using the DTMF generator (it is not necessary to switch the CPU system clock to OSC3).

Two frequency dividers are provided for the row group and column group. The actual generated frequencies are listed in Table 4.14.4.2. They may include an error within tolerance due to the dividing method.

Table 4.14.4.2 Standard vs actual frequency

ROW/COL	Tone output frequency (Hz)		Error (%) *
	Standard	Actual	
ROW1	697	701.32	+0.62
ROW2	770	771.45	+0.19
ROW3	852	857.17	+0.61
ROW4	941	935.10	-0.63
COL1	1209	1215.88	+0.57
COL2	1336	1331.68	-0.32
COL3	1477	1471.85	-0.35
COL4	1633	1645.01	+0.74

\* Errors (%) do not include oscillator drift.

The row group and column group dividers can be operated individually. The software can select one of them to output a single tone signal as well as a dual tone signal output. Use the SINR (FF16H•D1) and SINC (FF16H•D0) registers for this control.

Table 4.14.4.3 Tone output selection

Control register		Tone output
SINR	SINC	
0	0	DC level: 1/2 (VDD-VSS)
0	1	COL frequency
1	0	ROW frequency
1	1	Dual tone output

At initial reset, dual tone output is set.

The divided frequencies are converted into a tone signal through the sine-wave ROM and the D/A converter, then the tone signal is output from the TONE terminal.

The items to set before outputting a tone signal may be summarized as follows:

1. Setting tone mode ... It is not necessary if the mode has not be changed after an initial reset.
2. Selecting a tone output method (single tone/dual tone) ... SINR and SINC are used.
3. Turning the OSC3 oscillation circuit ON (OSCC = "1") ... Note

*Note: The OSC3 oscillation needs at least 5 msec until it is stabilized after the OSC3 oscillation circuit is turned ON. Therefore, dialing operations must be started after taking an interval of at least 5 msec from activation of the OSC3 oscillation circuit. Since the oscillation stabilization time varies depending on the external oscillator's characteristic and operating conditions, allow ample margin for the interval.*

*Further the OSC3 oscillation circuit increases current consumption, so it should be turned OFF when the DTMF generator is not used or the CPU does not need high-speed processing.*

The following explains how to output the tone signal and the circuit operation.

First, write "1" to the HSON register (FF18H•D3) so the dialer is in off-hook status. As a result, the DP terminal goes High (VDD) level.

Next, write the ROW/COL data of the pushbutton to be transmitted to the TCD3-TCD0 register (FF17H). Table 4.14.4.4 shows the relationship of write data and tone frequencies.

Table 4.14.4.4 Tone frequency selection

TCD code				Tone frequency	Key symbol	TCD code				Tone frequency	Key symbol
D3	D2	D1	D0			D3	D2	D1	D0		
0	0	0	0	(ROW1, COL4)	"A"	1	0	0	0	(ROW3, COL2)	"8"
0	0	0	1	(ROW1, COL1)	"1"	1	0	0	1	(ROW3, COL3)	"9"
0	0	1	0	(ROW1, COL2)	"2"	1	0	1	0	(ROW4, COL2)	"0"
0	0	1	1	(ROW1, COL3)	"3"	1	0	1	1	(ROW4, COL3)	"#"
0	1	0	0	(ROW2, COL1)	"4"	1	1	0	0	(ROW4, COL1)	"*"
0	1	0	1	(ROW2, COL2)	"5"	1	1	0	1	(ROW2, COL4)	"B"
0	1	1	0	(ROW2, COL3)	"6"	1	1	1	0	(ROW4, COL4)	"D"
0	1	1	1	(ROW3, COL1)	"7"	1	1	1	1	(ROW3, COL4)	"C"

Writing data to this register triggers the start of the tone output. When single tone output is selected, either the ROW frequency or COL frequency corresponding to the written data is output as a tone signal. When dual tone output is selected, the specified ROW and COL frequencies are output after they are composed.

Figure 4.14.4.2 shows a timing chart for tone output.

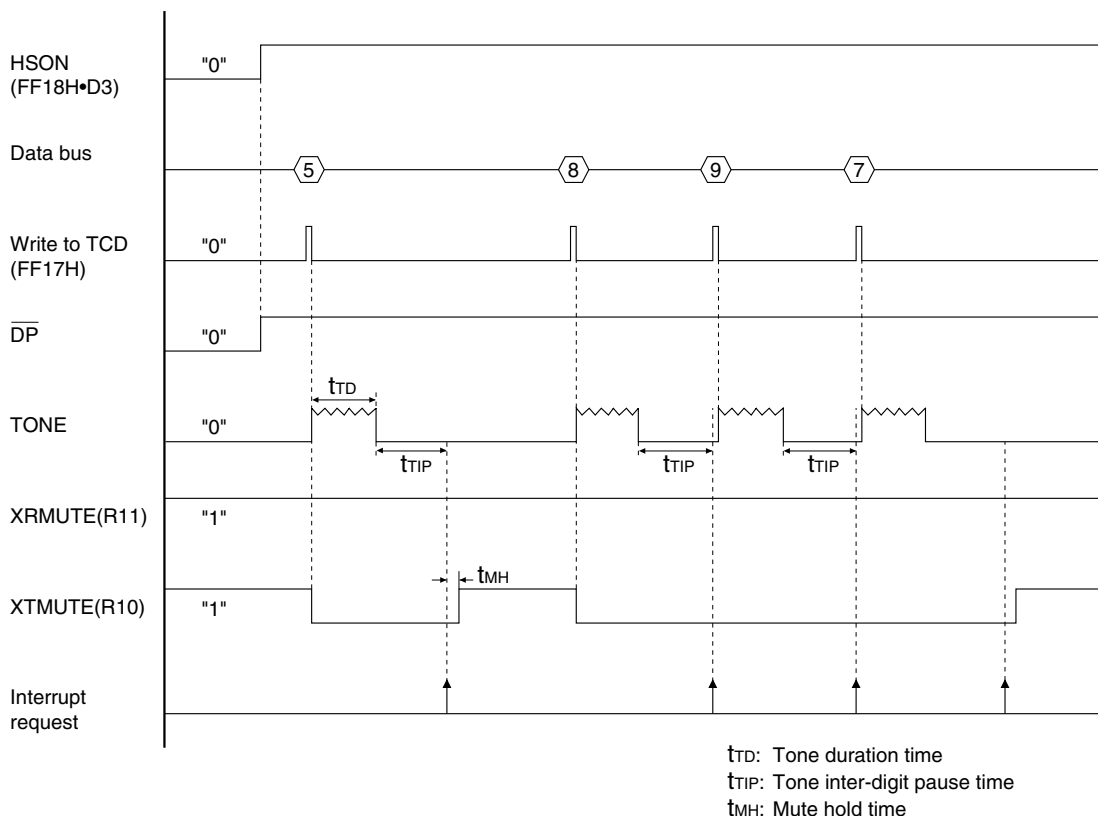

Fig. 4.14.4.2 Tone output timing chart

By writing data to the TCD register, the TONE terminal outputs the specified tone signal. At the same time, the XTMUTE (R10) terminal goes Low level.

The minimum tone duration time ( $t_{TD}$ ) can be selected as 94 msec or 47 msec when the DTS function is selected by mask option. The minimum tone duration time can be prolonged using the CTO register (FF16H•D3). When the CTO register is set to "1" before writing data to the TCD register, the tone output continues until "0" is written to the CTO register.

When the tone signal has been output completely, the TONE terminal returns to Low level, then a 94 msec of inter-digit pause will be inserted.

An interrupt occurs when the inter-digit pause time has passed. It allows transmission of the next tone.

The XTMUTE (R10) terminal keeps on Low level for 4 msec of mute hold time ( $t_{MH}$ ) after the inter-digit pause is released. If the next tone output does not start in this period, the XTMUTE (R10) terminal returns to High level. When the next tone output starts in the mute hold period, the XTMUTE (R10) terminal will stay in Low level.

Note that the CTMUT register (FF18H•D0) and CRMUT register (FF18H•D1) must be set to "1" when the above mute function (XTMUTE and XRMUTE control) is used.

The following summarizes a dialing procedure in the tone mode:

1. Write "1" to the HSON register.
2. Write "1" to the CTO register. (note)
3. Write the dial tone data to the TCD register. (tone output is started)
4. Count the tone duration time and then write "0" to the CTO register. (note)
5. Reset the interrupt factor flag after an interrupt has occurred.
6. Repeat steps 2 to 5 for the number of dial digits.

:

Communication

:

7. Write "0" to the HSON register after communication is finished.

*Note: The CTO register in 2 and 4 should be controlled if more than 94 msec tone duration time is required. It is not necessary when outputting a tone for 94 msec.*

### 4.14.5 Pulse mode (DP)

The pulse mode outputs dial pulses. By specifying a dial number using software, the DP generator generates the pulse pattern and outputs it from the  $\overline{DP}$  terminal.

At initial reset, the dialer is set in tone mode. To change the mode to the pulse mode, write "1" to the TPS register (FF10H•D3).

Figure 4.14.5.1 shows the block diagram of the DP generator.

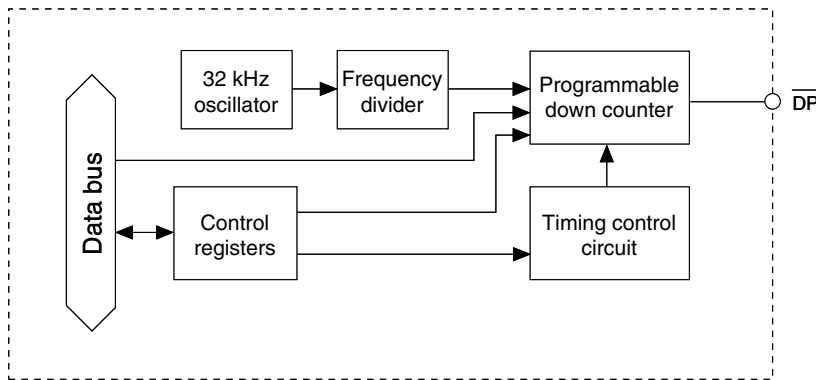

Fig. 4.14.5.1 DP generator block diagram

The DP generator uses the OSC1 (32 kHz) clock for generating dial pulses. In this mode it is not necessary to control the OSC3 oscillation circuit as in the tone mode.

In the pulse mode, the specified dial number (1 to 9) represents the number of pulses ("0" represents 10 pulses). The DP generator has a built-in programmable down counter in which a dial number can be preset. It produces dial pulses by means of a count down until it is equal to "0".

The pulse specification can be set by software and the timing control circuit controls the down counter according to the settings.

The software can set a pulse rate, make ratio and an inter-digit pause time.

The pulse rate is a number of output pulses per second, and can be selected to be either 10 pps (DRS = "0") or 20 pps (DRS = "1") using the DRS register. At initial reset, it is set to 10 pps (DRS = "0").

The make ratio (M:B) is the ratio of the make period (High) to the break period (Low). It can be selected to either 40:60 (MB = "0") or 33.3:66.6 (MB = "1") using the MB register (FF10H•D1). At initial reset, it is set to 40:60 (MB = "0").

The inter-digit pause time is the interval between digits of a dial number. It can be selected from among 15 types within 94 msec to 1,406 msec using the IDP3–IDP0 register (FF15H) as shown in Table 4.14.5.1.

Table 4.14.5.1 Selection of inter-digit pause time

IDP				Inter-digit pause time (msec)	IDP				Inter-digit pause time (msec)
D3	D2	D1	D0		D3	D2	D1	D0	
0	0	0	0	Unavailable *	1	0	0	0	750
0	0	0	1	94	1	0	0	1	844
0	0	1	0	188	1	0	1	0	938
0	0	1	1	281	1	0	1	1	1031
0	1	0	0	375	1	1	0	0	1125
0	1	0	1	469	1	1	0	1	1219
0	1	1	0	563	1	1	1	0	1313
0	1	1	1	656	1	1	1	1	1406

\* Do not write "0" (0000B) to the IDP register because it may cause a malfunction.

At initial reset, the inter-digit pause time is set to 750 msec (IDP = "1000B").

The following summarizes initial setting items that must be set before outputting dial pulses:

1. Set to pulse mode (TPS = "1").
2. Select a pulse rate (10 pps or 20 pps) using DRS.
3. Select a make ratio (40:60 or 33.3:66.6) using MB.
4. Select an inter-digit pause time (94 msec to 1,406 msec) using IDP.

The following explains how to output dial pulses and the circuit operation.

First, write "1" to the HSON register (FF18H•D3) so the dialer is in off-hook status. As a result, the  $\overline{DP}$  terminal goes High ( $V_{DD}$ ) level.

Next, write a digit of the dial number to be transmitted to the TCD3–TCD0 register (FF17H). Table 4.14.5.2 shows the relationship of write data and pulse counts.

Table 4.14.5.2 Pulse count selection

TCD code				Pulse count	TCD code				Pulse count
D3	D2	D1	D0		D3	D2	D1	D0	
0	0	0	0	Unavailable *	1	0	0	0	8
0	0	0	1	1	1	0	0	1	9
0	0	1	0	2	1	0	1	0	10
0	0	1	1	3	1	0	1	1	11
0	1	0	0	4	1	1	0	0	12
0	1	0	1	5	1	1	0	1	13
0	1	1	0	6	1	1	1	0	14
0	1	1	1	7	1	1	1	1	15

\* Do not write "0" (0000B) to the TCD register because it may cause a malfunction.

For a dial number between "1" to "9", the number is used for the pulse count as is. Dial number "0" represents 10 pulses, so write "10" (1010B) to the TCD register.

Writing data to the TCD register triggers the start of the pulse output.

Figure 4.14.5.2 shows a pulse output timing chart.

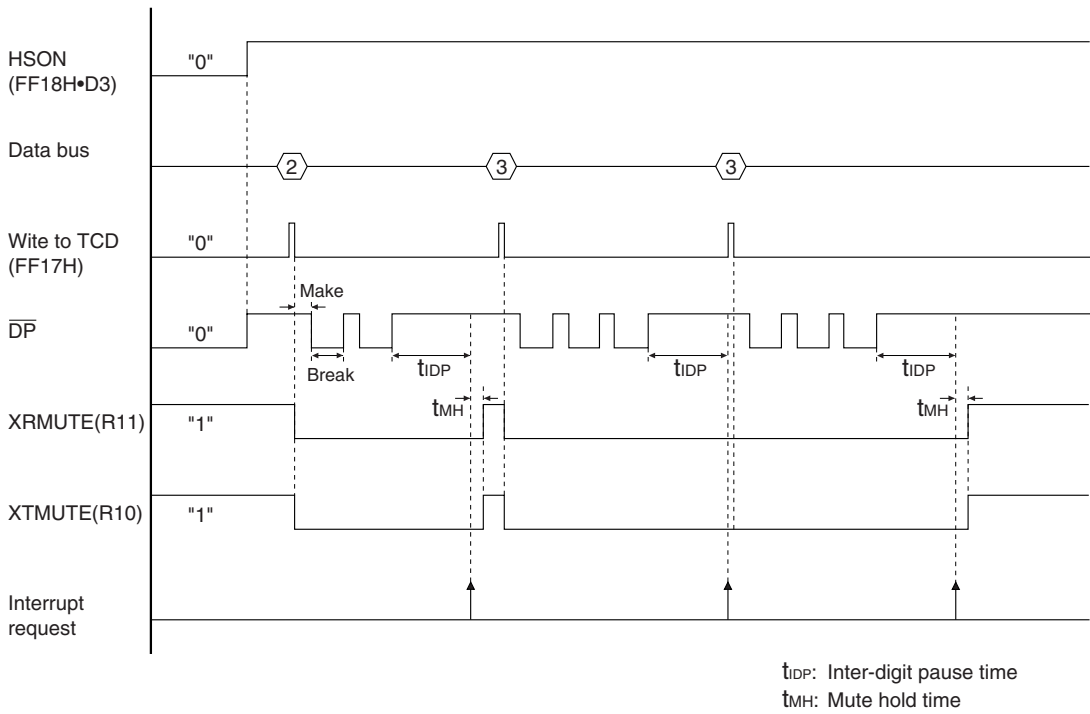

Fig. 4.14.5.2 Pulse output timing chart

When data is written to the TCD register, the specified number of pulses are output from the  $\overline{DP}$  terminal. At the same time, XRMUTE (R11) and XTMUTE (R10) terminals go Low level.

When the pulses have been output completely, the  $\overline{DP}$  terminal returns to High level, then the specified inter-digit pause will be inserted.

An interrupt occurs when the inter-digit pause time has passed. It allows transmission of the next dial pulses.

The XRMUTE (R11) and XTMUTE (R10) terminals keep on Low level for 4 msec of mute hold time (tMH) after the inter-digit pause is released. If the next pulse output does not start in this period, the XRMUTE (R11) and XTMUTE (R10) terminals return to High level. When the next pulse output starts in the mute hold period, the XRMUTE (R11) and XTMUTE (R10) terminals will stay in Low level.

Note that the CTMUT register (FF18H•D0) and CRMUT register (FF18H•D1) must be set to "1" when the above mute function (XTMUTE and XRMUTE control) is used.

The following summarizes a dialing procedure in the pulse mode:

1. Write "1" to the HSON register.
2. Write a dial number to the TCD register. (pulse output starts)
3. Reset the interrupt factor flag after an interrupt has occurred.
4. Repeat steps 2 to 3 for the number of dial digits.
- :
- Communication
- :
5. Write "0" to the HSON register after communication is finished.

### 4.14.6 Pause

This dialer allows insertion of a pause within 1 to 15 seconds between each two digits of tone signals or pulses. The pause time should be set to the PTS3–PTS0 register (FF11H) as shown in Table 4.14.6.1 before dialing.

Table 4.14.6.1 Pause time selection

PTS				Pause time (sec)	PTS				Pause time (sec)
D3	D2	D1	D0		D3	D2	D1	D0	
0	0	0	0	Unavailable *	1	0	0	0	8
0	0	0	1	1	1	0	0	1	9
0	0	1	0	2	1	0	1	0	10
0	0	1	1	3	1	0	1	1	11
0	1	0	0	4	1	1	0	0	12
0	1	0	1	5	1	1	0	1	13
0	1	1	0	6	1	1	1	0	14
0	1	1	1	7	1	1	1	1	15

\* Do not write "0" (0000B) to the PTS register because it may cause a malfunction.

At initial reset, the pause time is set to 4 seconds.

Writing data to the PTS register just defines the pause time. The actual pause operation will be activated when the PAUSE bit (FF14H•D1) is set to "1".

Figure 4.14.6.1 shows the timing chart of the pause function.

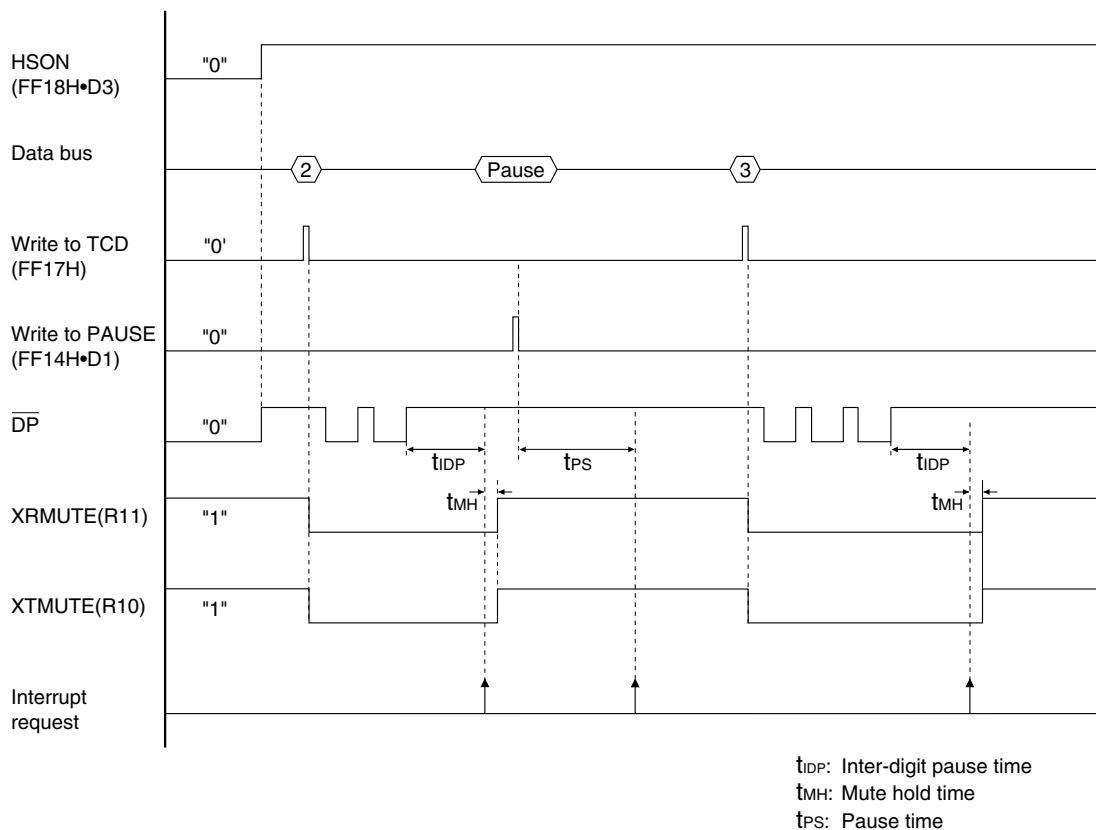

Fig. 4.14.6.1(a) Pause execution timing chart in pulse mode

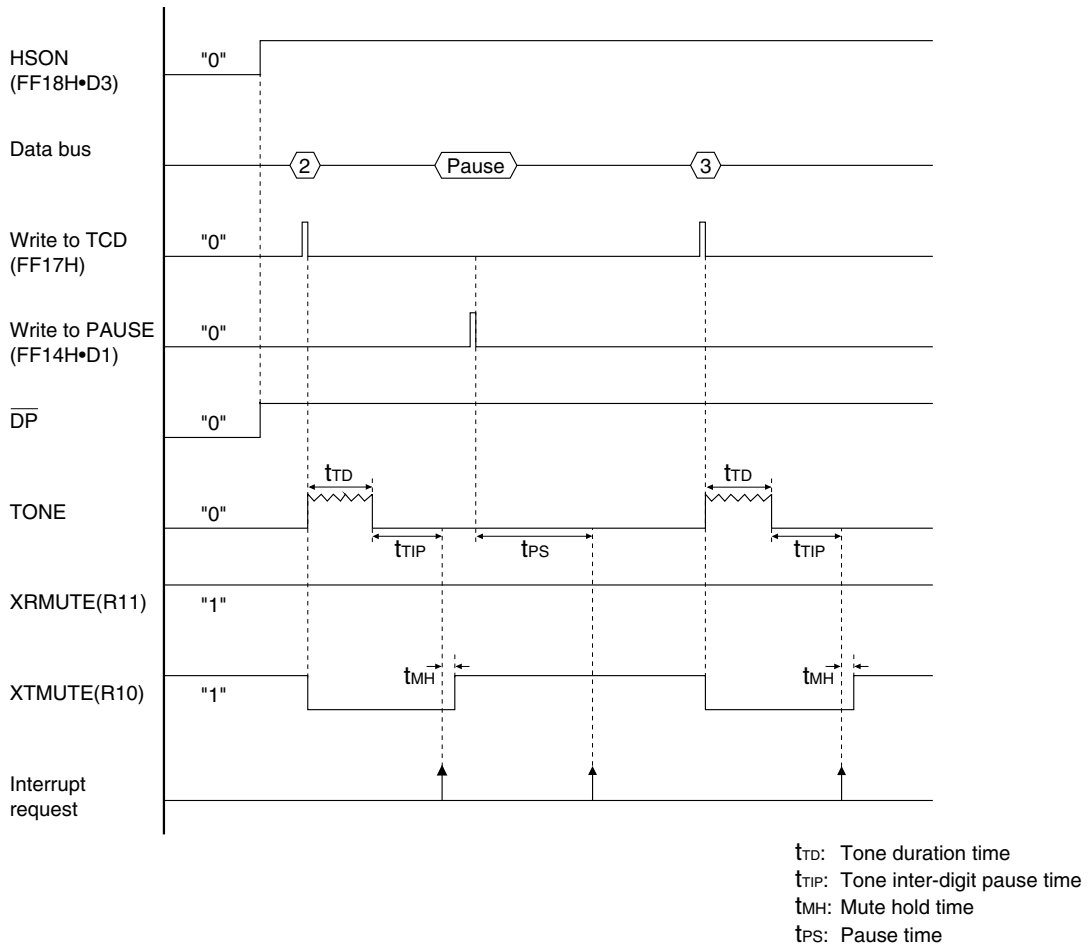

Fig. 4.14.6.1(b) Pause execution timing chart in tone mode

PAUSE is a write-only bit and is used as the trigger for a pause insertion.

When the pause time that is set to the PTS register has passed from the writing of the PAUSE bit, an interrupt occurs. At the same time the PAUSE bit is automatically cleared to "0" by the interrupt. Thus the pause function requires start control only.

The pause function uses the same interrupt system as the dialing completion. Therefore, the interrupt factor flag ID must be reset before executing the pause function.

### 4.14.7 Flash

The flash function pulls down the  $\overline{DP}$  terminal to Low level for a predetermined period of time to temporarily restore the telephone to on-hook status. The flash time should be set to the FTS3–FTS0 register (FF12H). Table 4.14.7.1 lists the available flash time.

Table 4.14.7.1 Flash time selection

FTS				Flash time (msec)	FTS				Flash time (msec)
D3	D2	D1	D0		D3	D2	D1	D0	
0	0	0	0	Unavailable *	1	0	0	0	750
0	0	0	1	94	1	0	0	1	844
0	0	1	0	188	1	0	1	0	938
0	0	1	1	281	1	0	1	1	1031
0	1	0	0	375	1	1	0	0	1125
0	1	0	1	469	1	1	0	1	1219
0	1	1	0	563	1	1	1	0	1313
0	1	1	1	656	1	1	1	1	1406

\* Do not write "0" (0000B) to the FTS register because it may cause a malfunction.

At initial reset, the flash time is set to 563 msec.

Writing data to the FTS register just defines the flash time. The actual flash operation will be activated when the FLASH bit (FF14H•D0) is set to "1".

Figure 4.14.7.1 shows a timing chart of the flash function.

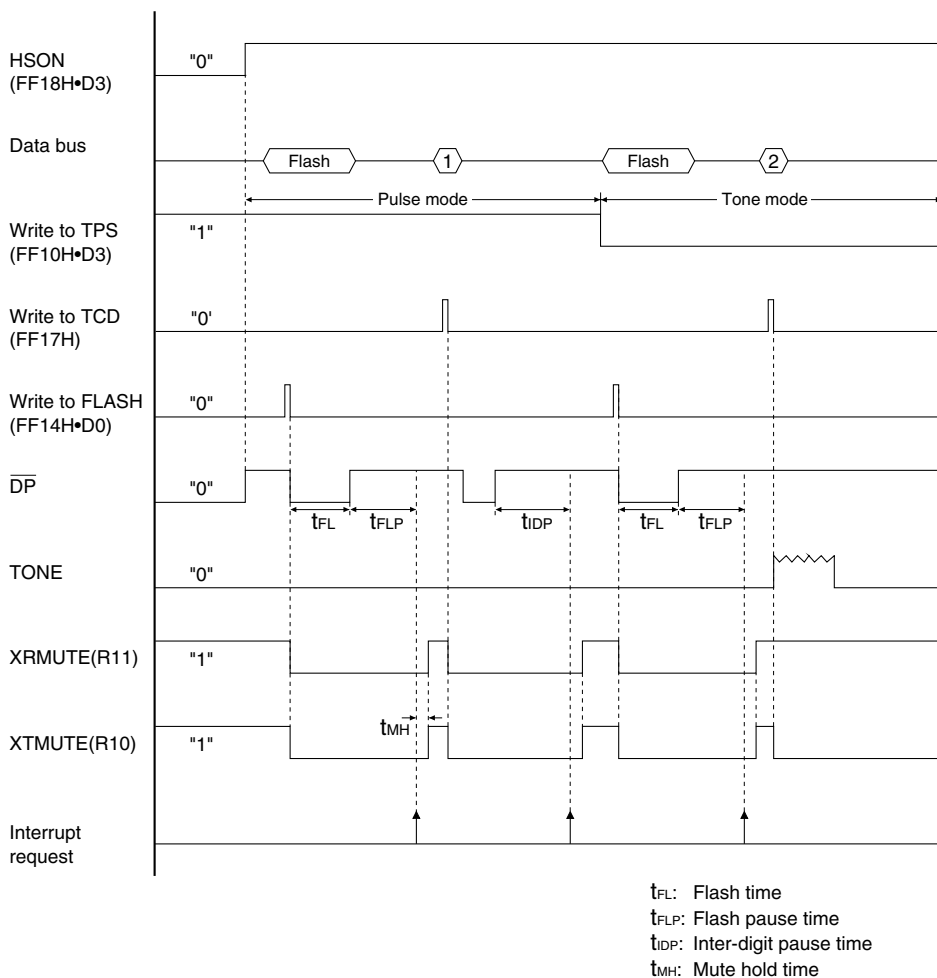

Fig. 4.14.7.1 Flash execution timing chart

FLASH is a write-only bit and is used as the trigger for a flash operation. When the FLASH bit is set to "1", the  $\overline{DP}$  terminal goes Low level until the flash time set by the FTS register has passed, then the  $\overline{DP}$  terminal returns to High level. After that 938 msec of the flash pause time is taken and an interrupt occurs. At the same time the FLASH bit is automatically cleared to "0" by the interrupt. Thus the flash function requires start control only.

The flash function uses the same interrupt system as the dialing completion. Therefore, the interrupt factor flag ID must be reset before executing the flash function.

#### 4.14.8 Hold-line

The hold-line function can assert the XTMUTE signal while holding the current communication line open. This function can be controlled using the HOLD register. When "1" is written to the HOLD register, the communication line is held open and the XTMUTE signal goes Low level. When "0" is written, the XTMUTE signal returns to High level.

The R12 terminal can be used to output the HDO signal that indicates hold status. To use the HDO signal, set the R12 port for the HDO output by writing "1" to the CHDO register (FF13H•D2). The R12 terminal will output the HDO signal by controlling the HOLD register. In this case, the output port data register R12 must be fixed at "1" and the high impedance control register at "0". Note that the HDO signal will be fixed at Low level if the R12 register is set to "0".

Figure 4.14.8.1 shows a timing chart of the hold-line function.

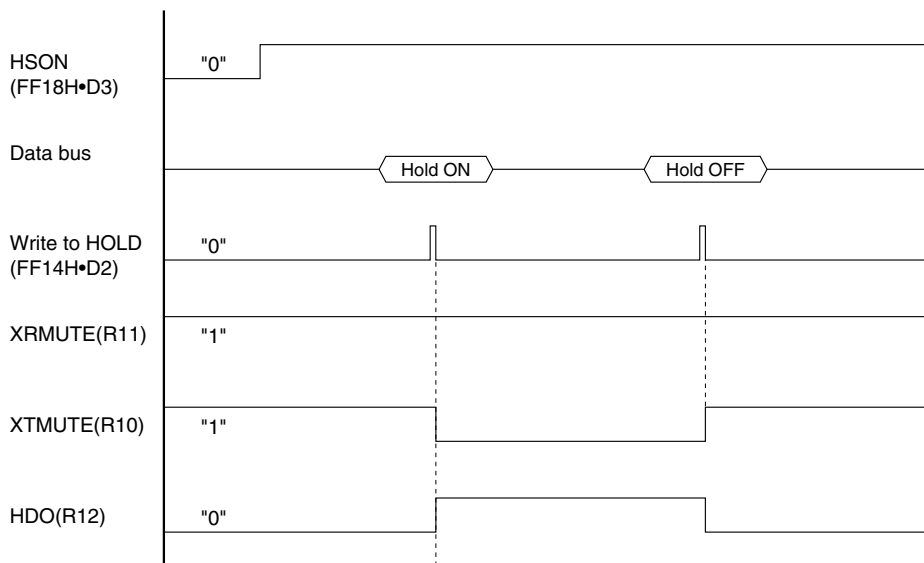

Fig. 4.14.8.1 Hold-line execution timing chart

### 4.14.9 Interrupt

The dialer has three types of interrupt generation functions.

#### (1) Dialing interrupt

##### *Tone mode*

In the tone mode, 94 msec of an inter-digit pause is made after a tone signal (min. 94 msec, can be prolonged by the CTO register) is output completely. A dialing interrupt occurs immediately following the inter-digit pause. See the timing chart in Figure 4.14.4.2.

##### *Pulse mode*

In the pulse mode, the inter-digit pause set by the IDP register is made after a dial pulse digit is output completely. A dialing interrupt occurs immediately following the inter-digit pause. See the timing chart in Figure 4.14.5.2.

#### (2) Pause interrupt

When the pause function is executed, an interrupt occurs when the pause time (1 to 15 sec) set by the PTS register has passed after writing "1" to the PAUSE bit. See the timing chart in Figure 4.14.6.1.

#### (3) Flash interrupt

When the flash function is executed, 938 msec of a flash pause is made when the flash time (94 to 1,406 msec) set by the FTS register has passed after writing "1" to the FLASH bit. A flash interrupt occurs immediately following the flash pause. See the timing chart in Figure 4.14.7.1.

The interrupt factor flag ID (FFF9H•D0) is set to "1" when an interrupt occurs. The interrupt request will be delivered to the CPU only when the interrupt mask register EID (FFE9H•D0) is set to "1".

If the EID register is set to "0", the interrupt request will be masked. However, the ID flag will be set at the above timing regardless of the EID register setting. So operation status can also be checked by reading the ID flag.

The ID flag is reset by writing "1". It must be reset for the next interrupt after an interrupt has occurred.

4.14.10 I/O memory of telephone function

Table 4.14.10.1 shows the I/O address and the control bits for the telephone function.

Table 4.14.10.1 Control bits of telephone function

Address	Register				Name	Init *1	1	0	Comment
	D3	D2	D1	D0					
FF00H	CLKCHG	OSCC	0	Dummy	CLKCHG	0	OSC3	OSC1	CPU clock switch

\*1 Initial value at initial reset

\*3 Constantly "0" when being read

\*2 Not set in the circuit

**R10HIZ–R13HIZ: R1 port high impedance control register (FF32)**

Controls high impedance output of the output port.

When "1" is written: High impedance

When "0" is written: Data output

Reading: Valid

When using the XTMUTE, XRMUTE, HDO and HFO outputs, fix these registers at "0". R10HIZ, R11HIZ, R12HIZ and R13HIZ correspond to the XTMUTE, XRMUTE, HDO and HFO outputs, respectively.

At initial reset, these registers are set to "0".

**R10–R13: R1 output port data register (FF33H)**

Set the output data for the output ports.

When "1" is written: High level output

When "0" is written: Low level output

Reading: Valid

When using the XTMUTE, XRMUTE, HDO and HFO outputs, fix these registers at "1". R10, R11, R12 and R13 correspond to the XTMUTE, XRMUTE, HDO and HFO outputs, respectively.

At initial reset, these registers are all set to "1".

**CTMO: R10 output selection register (FF13H•D0)**

Selects the R10 terminal function.

When "1" is written: XTMUTE output

When "0" is written: General-purpose DC output

Reading: Valid

When using the R10 terminal for the XTMUTE output, write "1" to this register. Furthermore, fix the R10 register at "1" and the R10HIZ register at "0".

The XTMUTE output is controlled by the CTMUT register (FF18H•D0).

At initial reset, this register is set to "0".

**CRMO: R11 output selection register (FF13H•D1)**

Selects the R11 terminal function.

When "1" is written: XRMUTE output

When "0" is written: General-purpose DC output

Reading: Valid

When using the R11 terminal for the XRMUTE output, write "1" to this register. Furthermore, fix the R11 register at "1" and the R11HIZ register at "0".

The XRMUTE output is controlled by the CRMUT register (FF18H•D1).

At initial reset, this register is set to "0".

**CHDO: R12 output selection register (FF13H•D2)**

Selects the R12 terminal function.

When "1" is written: HDO output

When "0" is written: General-purpose DC output

Reading: Valid

When using the R12 terminal for the HDO output, write "1" to this register. Furthermore, fix the R12 register at "1" and the R12HIZ register at "0".

The HDO output is controlled by the HOLD register (FF14H•D2).

At initial reset, this register is set to "0".

**CHFO: R13 output selection register (FF13H•D3)**

Selects the R13 terminal function.

When "1" is written: HFO output

When "0" is written: General-purpose DC output

Reading: Valid

When using the R13 terminal for the HFO output, write "1" to this register. Furthermore, fix the R13 register at "1" and the R13HIZ register at "0".

The HFO output is controlled by the HF register (FF14H•D3).

At initial reset, this register is set to "0".

**OSCC: OSC3 oscillation control (FF00H•D2)**

Controls the OSC3 oscillation.

When "1" is written: OSC3 oscillation ON

When "0" is written: OSC3 oscillation OFF

Reading: Valid

When it is necessary to activate the DTMF generator or to operate the CPU at high speed, set OSCC to "1". At other times, set it to "0" to reduce current consumption.

At initial reset, this register is set to "0".

**TPS: Tone/Pulse mode selection (FF10H•D3)**

Selects a dialing mode.

When "1" is written: Pulse mode

When "0" is written: Tone mode

Reading: Valid

When "1" is written to the TPS register, pulse mode (outputs dial pulses) is selected. When "0" is written, tone mode (outputs tone signals) is selected.

At initial reset, this register is set to "0".

**MB: Make/Break ratio selection (FF10H•D1)**

Selects a make ratio for pulse mode.

When "1" is written: 33.3 : 66.6

When "0" is written: 40.0 : 60.0

Reading: Valid

The make ratio (make : break) of the dialing pulses that are generated from the DP generator is set. When "1" is written to the MB register, 33.3 : 66.6 is set. When "0" is written, 40.0 : 60.0 is set. The DP generator produces the dialing pulses as "Make" (High) period is before "Break" (Low) period.

This selection is valid only for pulse mode.

At initial reset, this register is set to "0".

**DRS: Dialing pulse rate selection (FF10H•D0)**

Selects a dialing pulse rate for pulse mode.

When "1" is written: 20 pps (pulses per second)

When "0" is written: 10 pps (pulses per second)

Reading: Valid

The pulse rate (number of pulses per second) for the dialing pulses that are generated from the DP generator is set. When "1" is written to the DRS register, 20 pps is set. When "0" is written, 10 pps is set.

This selection is valid only for pulse mode.

At initial reset, this register is set to "0".

**PTS0–PTS3: Pause time selection (FF11H)**

Selects a pause time from among the 15 types shown in Table 4.14.10.2.

Table 4.14.10.2 Selection of pause times

PTS				Pause time (sec)	PTS				Pause time (sec)
D3	D2	D1	D0		D3	D2	D1	D0	
0	0	0	0	Unavailable *	1	0	0	0	8
0	0	0	1	1	1	0	0	1	9
0	0	1	0	2	1	0	1	0	10
0	0	1	1	3	1	0	1	1	11
0	1	0	0	4	1	1	0	0	12
0	1	0	1	5	1	1	0	1	13
0	1	1	0	6	1	1	1	0	14
0	1	1	1	7	1	1	1	1	15

\* Do not write "0" (0000B) to the PTS register because it may cause a malfunction.

The specified pause time will be inserted when "1" is written to the PAUSE bit (FF14H•D1).

At initial reset, this register is set to "0100B" (4 seconds).

**FTS0–FTS3: Flash time selection (FF12H)**

Selects a flash time from among the 15 types shown in Table 4.14.10.3.

Table 4.14.10.3 Selection of flash times

FTS				Flash time (msec)	FTS				Flash time (msec)
D3	D2	D1	D0		D3	D2	D1	D0	
0	0	0	0	Unavailable *	1	0	0	0	750
0	0	0	1	94	1	0	0	1	844
0	0	1	0	188	1	0	1	0	938
0	0	1	1	281	1	0	1	1	1031
0	1	0	0	375	1	1	0	0	1125
0	1	0	1	469	1	1	0	1	1219
0	1	1	0	563	1	1	1	0	1313
0	1	1	1	656	1	1	1	1	1406

\* Do not write "0" (0000B) to the FTS register because it may cause a malfunction.

The specified flash time will be inserted when "1" is written to the FLASH bit (FF14H•D0).

At initial reset, this register is set to "0110B" (563 msec).

**HOLD: Hold-line function (FF14H•D2)**

Controls the hold-line function and HDO signal output.

When "1" is written: ON (High level output on R12 terminal)

When "0" is written: OFF (Low level output on R12 terminal)

Reading: Valid

This register controls the HDO signal output to the R12 terminal when the HDO function has been selected. The HDO output function is set by writing "1" to the CHDO register (FF13H•D2). In this case, the R12 register must be fixed at "1" and the R12HIZ register at "0".

When "1" is written to the HOLD register, the XTMUTE (R10) terminal goes Low (V<sub>SS</sub>) level and the HDO (R12) terminal goes High (V<sub>DD</sub>) level.

When "0" is written, the XTMUTE (R10) terminal goes High (V<sub>DD</sub>) level and the HDO (R12) terminal goes Low (V<sub>SS</sub>) level.

At initial reset, this register is set to "0".

**PAUSE: Pause function (FF14H•D1)**

Executes the pause function.

- When "1" is written: Execute pause function
- When "0" is written: Cancel pause function
- Reading: Always "0"

Writing "1" to PAUSE executes the pause function. The pause time set by the PTS register is inserted to the  $\overline{DP}$  output signal. An interrupt occurs when the pause is released and the PAUSE bit is automatically cleared to "0".

This bit is write-only, and so is always "0" at reading.

**FLASH: Flash function (FF14H•D0)**

Executes the flash function.

- When "1" is written: Execute flash function
- When "0" is written: Cancel flash function
- Reading: Always "0"

Writing "1" to FLASH executes the flash function. The  $\overline{DP}$ , XRMUTE (R11) and XTMUTE (R10) terminals go Low (Vss) level during the flash period set by the FTS register and then an interrupt occurs. At the same time the FLASH bit is automatically cleared to "0" by the interrupt.

This bit is write-only, and so is always "0" at reading.

**HF: Handfree (FF14H•D3)**

Controls the handfree function and HFO signal output.

- When "1" is written: ON (High level output on R13 terminal)
- When "0" is written: OFF (Low level output on R13 terminal)
- Reading: Valid

This register controls the HFO signal output to the R13 terminal when the HFO function has been selected. The HFO output function is set by writing "1" to the CHFO register (FF13H•D3). In this case, the R13 register must be fixed at "1" and the R13HIZ register at "0".

When "1" is written to the HF register, the HFO (R13) terminal goes High (VDD) level.

When "0" is written, the HFO (R13) terminal goes Low (Vss) level.

At initial reset, this register is set to "0".

**IDP0-IDP3: Inter-digit pause time selection (FF15H)**

Select an inter-digit pause time for the pulse mode from among the 15 types shown in Table 4.14.10.4.

Table 4.14.10.4 Selection of inter-digit pause times

IDP				Inter-digit pause time (msec)	IDP				Inter-digit pause time (msec)
D3	D2	D1	D0		D3	D2	D1	D0	
0	0	0	0	Unavailable *	1	0	0	0	750
0	0	0	1	94	1	0	0	1	844
0	0	1	0	188	1	0	1	0	938
0	0	1	1	281	1	0	1	1	1031
0	1	0	0	375	1	1	0	0	1125
0	1	0	1	469	1	1	0	1	1219
0	1	1	0	563	1	1	1	0	1313
0	1	1	1	656	1	1	1	1	1406

\* Do not write "0" (0000B) to the IDP register because it may cause a malfunction.

The specified inter-digit pause time will be inserted after each dialing pulse digit. This selection is valid only for pulse mode.

At initial reset, this register is set to "1000B" (750 msec).

**SINR: DTMF row frequencies output enable (FF16H•D1)**

Enables or disables the DTMF row frequency output.

When "1" is written: Enabled

When "0" is written: Disabled

Reading: Valid

This register is used to set the tone output mode with the SINC register. Write "1" to this register when performing dual-tone output or single-tone ROW frequency output.

At initial reset, this register is set to "1".

**SINC: DTMF column frequencies output enable (FF16H•D0)**

Enables or disables the DTMF column frequency output.

When "1" is written: Enabled

When "0" is written: Disabled

Reading: Valid

This register is used to set the tone output mode with the SINR register. Write "1" to this register when performing dual-tone output or single-tone COL frequency output.

At initial reset, this register is set to "1".

Table 4.14.10.5 lists the tone output selection using the SINR and SINC registers.

Table 4.14.10.5 Selection of tone output

Control register		Tone output
SINR	SINC	
0	0	DC level: 1/2 (VDD–VSS)
0	1	COL frequency
1	0	ROW frequency
1	1	Dual tone output

Tables 4.14.10.6(a) and (b) list the frequencies set by the TCD register (FF17H) when single tone output is selected.

Table 4.14.10.6(a) Single-tone COL frequencies (SINR = "0", SINC = "1")

TCD code				COL frequency (Hz)	TCD code				COL frequency (Hz)
D3	D2	D1	D0		D3	D2	D1	D0	
0	0	0	0	COL4: 1645.01	1	0	0	0	COL2: 1331.68
0	0	0	1	COL1: 1215.88	1	0	0	1	COL3: 1471.85
0	0	1	0	COL2: 1331.68	1	0	1	0	COL2: 1331.68
0	0	1	1	COL3: 1471.85	1	0	1	1	COL3: 1471.85
0	1	0	0	COL1: 1215.88	1	1	0	0	COL1: 1215.88
0	1	0	1	COL2: 1331.68	1	1	0	1	COL4: 1645.01
0	1	1	0	COL3: 1471.85	1	1	1	0	COL4: 1645.01
0	1	1	1	COL1: 1215.88	1	1	1	1	COL4: 1645.01

Table 4.14.10.6(b) Single-tone ROW frequencies (SINR = "1", SINC = "0")

TCD code				ROW frequency (Hz)	TCD code				ROW frequency (Hz)
D3	D2	D1	D0		D3	D2	D1	D0	
0	0	0	0	ROW1: 701.32	1	0	0	0	ROW3: 857.17
0	0	0	1	ROW1: 701.32	1	0	0	1	ROW3: 857.17
0	0	1	0	ROW1: 701.32	1	0	1	0	ROW4: 935.10
0	0	1	1	ROW1: 701.32	1	0	1	1	ROW4: 935.10
0	1	0	0	ROW2: 771.45	1	1	0	0	ROW4: 935.10
0	1	0	1	ROW2: 771.45	1	1	0	1	ROW2: 771.45
0	1	1	0	ROW2: 771.45	1	1	1	0	ROW4: 935.10
0	1	1	1	ROW3: 857.17	1	1	1	1	ROW3: 857.17

**DTS: Tone duration time selection (FF16H•D2)**

Selects the tone duration time. (Mask option)

- When "1" is written: 47 msec
- When "0" is written: 94 msec
- Reading: Valid

When "1" is written to the DTS register, the minimum tone duration time is set to 47 msec and when "0" is written, it is set to 97 msec.

Note that this register is effective when the DTS function is selected by mask option. If mask option is selected as "not use", the minimum tone duration time will be fixed at 94 msec.

At initial reset, this register is set to "0".

**TCD0–TCD3: Telephone code for dialing (FF17H)**

By writing code to this register, the dialer starts outputting the corresponding dial pulses (in pulse mode) or tone signals (in tone mode). When the output is finished, an interrupt occurs.

At initial reset, this register is set to "0000B".

The following shows the register settings for each mode.

**(1) Pulse mode**

In this mode, write data for a dial number (1–9, 0) to this register.

Table 4.14.10.7 lists the relationship of writing codes and pulse counts.

*Table 4.14.10.7 Relationship of code sand pulse counts*

TCD code				Pulse count	TCD code				Pulse count
D3	D2	D1	D0		D3	D2	D1	D0	
0	0	0	0	Unavailable *	1	0	0	0	8
0	0	0	1	1	1	0	0	1	9
0	0	1	0	2	1	0	1	0	10
0	0	1	1	3	1	0	1	1	11
0	1	0	0	4	1	1	0	0	12
0	1	0	1	5	1	1	0	1	13
0	1	1	0	6	1	1	1	0	14
0	1	1	1	7	1	1	1	1	15

\* Do not write "0" (0000B) to the TCD register because it may cause a malfunction.

For a dial number between "1" to "9", the number is used for the pulse count as is. Dial number "0" represents 10 pulses, so write "10" (1010B) to the TCD register.

**(2) Tone mode**

In this mode, write data for a push button (ROW, COL) to this register.

Table 4.14.10.8 lists the relationship of writing codes and tone frequencies.

*Table 4.14.10.8 Relationship of codes and tone frequencies*

TCD code				Tone frequency	Key symbol	TCD code				Tone frequency	Key symbol
D3	D2	D1	D0			D3	D2	D1	D0		
0	0	0	0	(ROW1, COL4)	"A"	1	0	0	0	(ROW3, COL2)	"8"
0	0	0	1	(ROW1, COL1)	"1"	1	0	0	1	(ROW3, COL3)	"9"
0	0	1	0	(ROW1, COL2)	"2"	1	0	1	0	(ROW4, COL2)	"0"
0	0	1	1	(ROW1, COL3)	"3"	1	0	1	1	(ROW4, COL3)	"#"
0	1	0	0	(ROW2, COL1)	"4"	1	1	0	0	(ROW4, COL1)	"*"
0	1	0	1	(ROW2, COL2)	"5"	1	1	0	1	(ROW2, COL4)	"B"
0	1	1	0	(ROW2, COL3)	"6"	1	1	1	0	(ROW4, COL4)	"D"
0	1	1	1	(ROW3, COL1)	"7"	1	1	1	1	(ROW3, COL4)	"C"

Writing data to this register triggers the start of the tone output. When single tone output is selected, either the ROW frequency or COL frequency corresponding to the written data is output as a tone signal. When dual tone output is selected, the specified ROW and COL frequencies are output after they are composed.

**CRMUT: Receive mute control (FF18H•D1)**

Controls the receive mute.

When "1" is written: Receive mute output

When "0" is written: Low level output on XRMUTE (R11) terminal

Reading: Valid

When "0" is written to the CRMUTE register, the XRMUTE (R11) terminal is pulled down to Low (V<sub>SS</sub>) level to mute the receive line.

When the CRMUTE register is set to "1", the XRMUTE (R11) terminal is controlled by the hardware and will be Low (V<sub>SS</sub>) level during a dialing pulse cycle or a flash cycle.

At initial reset, this register is set to "1".

**CTMUT: Transmit mute control (FF18H•D0)**

Controls the transmit mute.

When "1" is written: Transmit mute output

When "0" is written: Low level output on XTMUTE (R10) terminal

Reading: Valid

When "0" is written to the CTMUTE register, the XTMUTE (R10) terminal is pulled down to Low (V<sub>SS</sub>) level to mute the transmit line.

When the CTMUTE register is set to "1", the XTMUTE (R10) terminal is controlled by the hardware and will be Low (V<sub>SS</sub>) level during a dialing pulse cycle, flash cycle, dialing tone cycle or a hold-line cycle.

At initial reset, this register is set to "1".

**HSON: Hook switch ON/OFF (FF18H•D0)**

Controls the hook switch.

When "1" is written: Hook OFF

When "0" is written: Hook ON

Reading: Valid

When the HSON register is set to "1", the  $\overline{DP}$  terminal goes High (V<sub>DD</sub>) level and the hook switch goes to off-hook status.

At initial reset, this register is set to "0".

**CTO: Continuous output tone selection (FF16H•D3)**

Selects the tone duration time to continuous output or not.

When "1" is written: Continuous

When "0" is written: 94 msec

Reading: Valid

This register is used to decide the tone duration time. The minimum value of tone duration time is 94 msec.

When the CTO register is set to "1", a tone signal will be output until the CTO register is changed to "0". If the period (CTO is changed from "1" to "0"), that is controlled by the CTO register, is less than the minimum tone duration time (94 or 47 msec), the duration time will be prolonged to the minimum tone duration time.

When the CTO register is set to "0", a tone signal will be output with the minimum tone duration time.

This setting is valid only for tone mode.

At initial reset, this register is set to "0".

**EID: Interrupt mask register (FFE9H•D0)**

Enables or disables the generation of an interrupt for the CPU.

- When "1" is written: Enabled
- When "0" is written: Disabled
- Reading: Valid

EID is the interrupt mask register corresponding to the dialing interrupt factor. Interrupts set to "1" are enabled and interrupts set to "0" are disabled.

At initial reset, this register is set to "0".

**ID: Interrupt factor flag (FFF9H•D0)**

Indicates the dialing interrupt generation status.

- When "1" is read: Interrupt has occurred
- When "0" is read: Interrupt has not occurred
- When "1" is written: Flag is reset
- When "0" is written: Invalid

The interrupt factor flag ID is set to "1" when a dialing interrupt factor occurs (when a dialing output, pause or flash cycle is completed). After executing a dialing function (dialing number, pause, flash), this flag must be reset. Otherwise, the next dialing function can not be executed.

The interrupt factor flag is reset to "0" by writing "1".

After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.

At initial reset, this flag is set to "0".

**4.14.11 Programming notes**

- (1) It is necessary to turn the OSC3 oscillation on prior to a dialing operation in tone mode because the tone mode uses the OSC3 (3.58 MHz) clock. However it increases current consumption. Therefore, turn the OSC3 oscillation off after finishing the dialling operation in tone mode.
- (2) Do not write "0" (0000B) to the IDP, FTS, PTS or TCD (in pulse mode) registers because it may cause a malfunction.
- (3) The pause function control bit PAUSE (FF14H•D1) and the flash function control bit FLASH (FF14H•D0) are write-only, so software cannot control these functions (on address FF14H) using an ALU instruction (AND, OR ...). Furthermore, be aware that the pause function or the flash function is canceled when "0" is written to the PAUSE bit (FF14H•D1) or the FLASH bit (FF14H•D0).
- (4) After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.

## 4.15 Interrupt and HALT

---

### <Interrupt types>

The E0C63567 provides the following interrupt functions.

External interrupt:	• Input interrupt	(2 systems)
Internal interrupt:	• Watchdog timer interrupt	(NMI, 1 system)
	• Programmable timer interrupt	(2 systems)
	• Serial interface interrupt	(3 systems)
	• Timer interrupt	(4 systems)
	• Stopwatch timer interrupt	(2 systems)
	• Dialing interrupt	(1 system)

To authorize interrupt, the interrupt flag must be set to "1" (EI) and the necessary related interrupt mask registers must be set to "1" (enable).

When an interrupt occurs the interrupt flag is automatically reset to "0" (DI), and interrupts after that are inhibited.

The watchdog timer interrupt is an NMI (non-maskable interrupt), therefore, the interrupt is generated regardless of the interrupt flag setting. Also the interrupt mask register is not provided. However, it is possible to not generate NMI since software can stop the watchdog timer operation.

Figure 4.15.1 shows the configuration of the interrupt circuit.

*Note: After an initial reset, all the interrupts including NMI are masked until both the stack pointers SP1 and SP2 are set with the software. Be sure to set the SP1 and SP2 in the initialize routine. Further, when re-setting the stack pointer, the SP1 and SP2 must be set as a pair. When one of them is set, all the interrupts including NMI are masked and interrupts cannot be accepted until the other one is set.*

### <HALT>

The E0C63567 has HALT functions that considerably reduce the current consumption when it is not necessary.

The CPU enters HALT status when the HALT instruction is executed.

In HALT status, the operation of the CPU is stopped. However, timers continue counting since the oscillation circuit operates. Reactivating the CPU from HALT status is done by generating a hardware interrupt request including NMI.

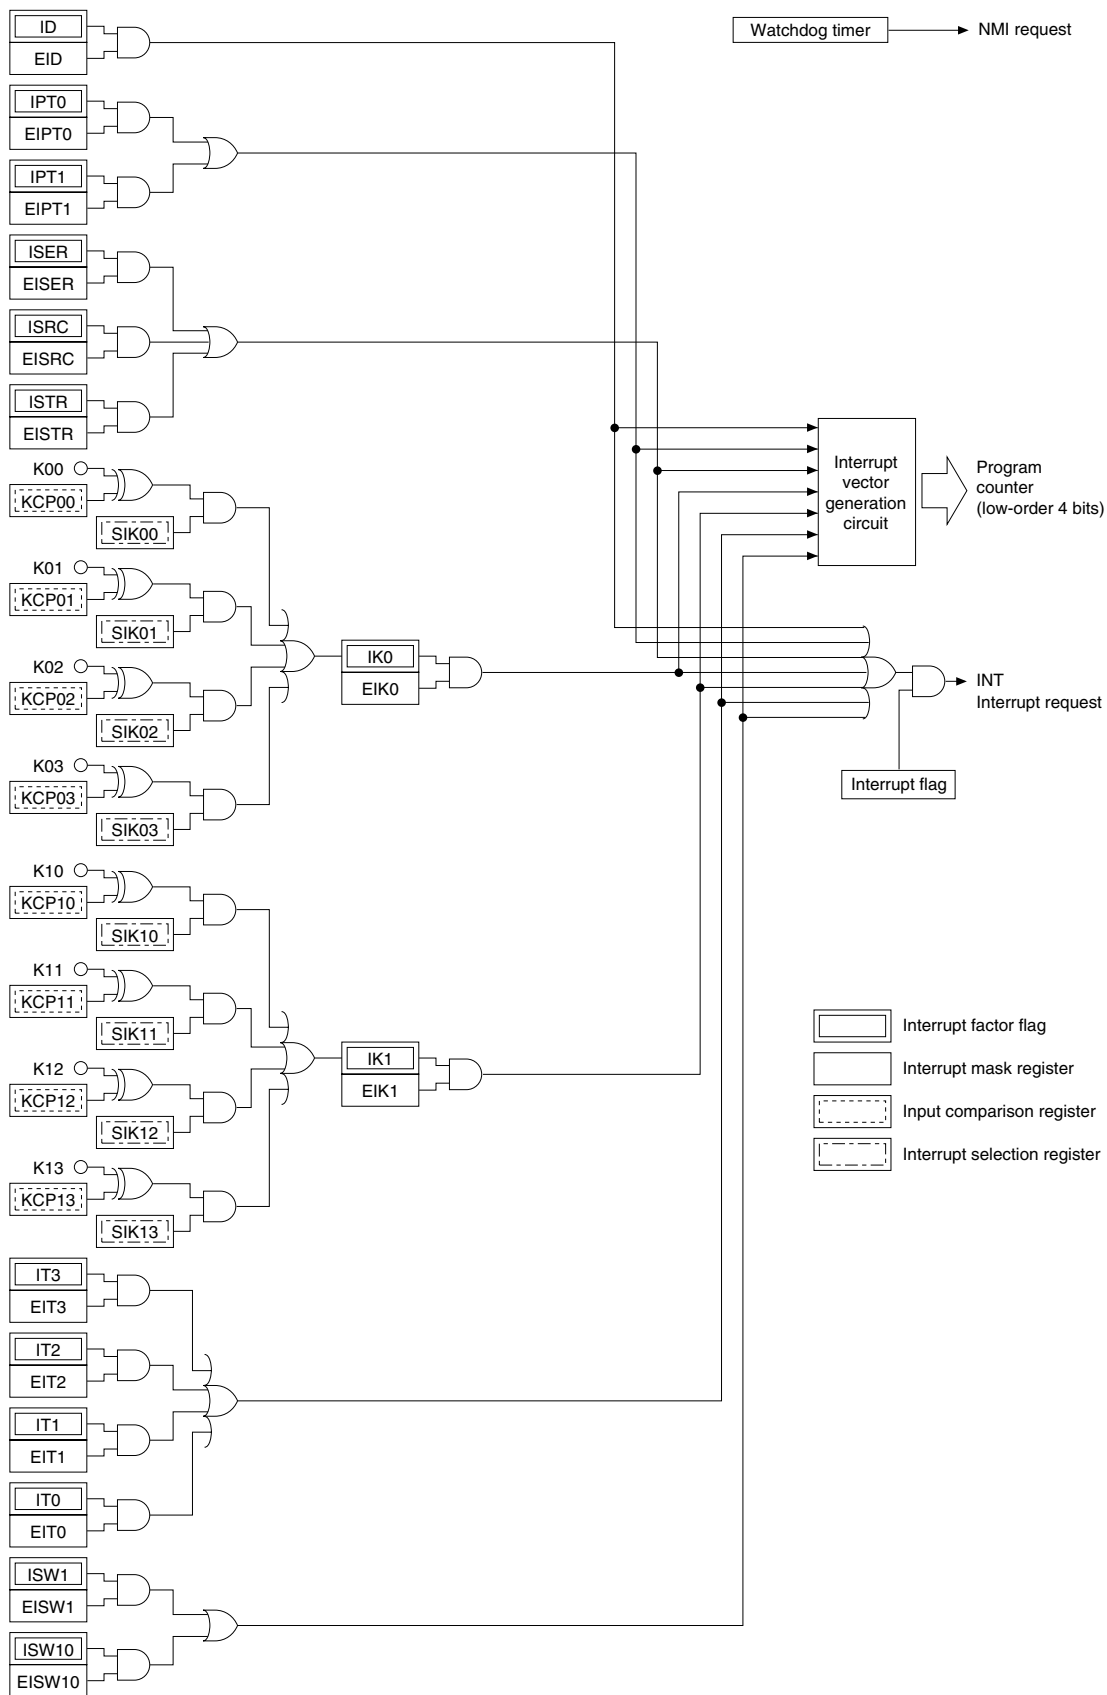

Fig. 4.15.1 Configuration of the interrupt circuit

### 4.15.1 Interrupt factor

Table 4.15.1.1 shows the factors for generating interrupt requests.

The interrupt flags are set to "1" depending on the corresponding interrupt factors.

The CPU operation is interrupted when an interrupt factor flag is set to "1" if the following conditions are established.

- The corresponding mask register is "1" (enabled)
- The interrupt flag is "1" (EI)

The interrupt factor flag is reset to "0" when "1" is written.

At initial reset, the interrupt factor flags are reset to "0".

- \* Since the watchdog timer's interrupt is NMI, the interrupt is generated regardless of the setting above, and no interrupt factor flag is provided.

Table 4.15.1.1 Interrupt factors

Interrupt factor	Interrupt factor flag
Dialer (dialing cycle completion)	ID (FFF9H•D0)
Programmable timer 1 (counter = 0)	IPT1 (FFF2H•D1)
Programmable timer 0 (counter = 0)	IPT0 (FFF2H•D0)
Serial interface (receive error)	ISER (FFF3H•D2)
Serial interface (receive completion)	ISRC (FFF3H•D0)
Serial interface (transmit completion)	ISTR (FFF3H•D1)
K00–K03 input (falling edge or rising edge)	IK0 (FFF4H•D0)
K10–K13 input (falling edge or rising edge)	IK1 (FFF5H•D0)
Clock timer 1 Hz (falling edge)	IT3 (FFF6H•D3)
Clock timer 2 Hz (falling edge)	IT2 (FFF6H•D2)
Clock timer 8 Hz (falling edge)	IT1 (FFF6H•D1)
Clock timer 32 Hz (falling edge)	IT0 (FFF6H•D0)
Stopwatch timer (1 Hz)	ISW1 (FFF7H•D1)
Stopwatch timer (10 Hz)	ISW10 (FFF7H•D0)

*Note:* After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.

### 4.15.2 Interrupt mask

The interrupt factor flags can be masked by the corresponding interrupt mask registers.

The interrupt mask registers are read/write registers. They are enabled (interrupt authorized) when "1" is written to them, and masked (interrupt inhibited) when "0" is written to them.

At initial reset, the interrupt mask register is set to "0".

Table 4.15.2.1 shows the correspondence between interrupt mask registers and interrupt factor flags.

Table 4.15.2.1 Interrupt mask registers and interrupt factor flags

Interrupt mask register		Interrupt factor flag	
EID	(FFE9H•D0)	ID	(FFF9H•D0)
EIPT1	(FFE2H•D1)	IPT1	(FFF2H•D1)
EIPT0	(FFE2H•D0)	IPT0	(FFF2H•D0)
EISER	(FFE3H•D2)	ISER	(FFF3H•D2)
EISRC	(FFE3H•D0)	ISRC	(FFF3H•D0)
EISTR	(FFE3H•D1)	ISTR	(FFF3H•D1)
EIK0	(FFE4H•D0)	IK0	(FFF4H•D0)
EIK1	(FFE5H•D0)	IK1	(FFF5H•D0)
EIT3	(FFE 6H•D3)	IT3	(FFF6H•D3)
EIT2	(FFE6H•D2)	IT2	(FFF6H•D2)
EIT1	(FFE6H•D1)	IT1	(FFF6H•D1)
EIT0	(FFE6H•D0)	IT0	(FFF6H•D0)
EISW1	(FFE7H•D1)	ISW1	(FFF7H•D1)
EISW10	(FFE7H•D0)	ISW10	(FFF7H•D0)

### 4.15.3 Interrupt vector

When an interrupt request is input to the CPU, the CPU begins interrupt processing. After the program being executed is terminated, the interrupt processing is executed in the following order.

- 1 The content of the flag register is evacuated, then the I flag is reset.
- 2 The address data (value of program counter) of the program to be executed next is saved in the stack area (RAM).
- 3 The interrupt request causes the value of the interrupt vector (0100H–010EH) to be set in the program counter.
- 4 The program at the specified address is executed (execution of interrupt processing routine by software).

Table 4.15.3.1 shows the correspondence of interrupt requests and interrupt vectors.

Table 4.15.3.1 Interrupt request and interrupt vectors

Interrupt vector	Interrupt factor	Priority
0100H	Watchdog timer	High ↑
0102H	Dialer	
0104H	Programmable timer	
0106H	Serial interface	
0108H	K00–K03 input	
010AH	K10–K13 input	↓ Low
010CH	Clock timer	
010EH	Stopwatch timer	

The four low-order bits of the program counter are indirectly addressed through the interrupt request.

4.15.4 I/O memory of interrupt

Tables 4.15.4.1(a) and (b) show the I/O addresses and the control bits for controlling interrupts.

Table 4.15.4.1(a) Control bits of interrupt (1)

Address	Register				Name	Init *1	1	0	Comment
	D3	D2	D1	D0

**ISW1, ISW10: Interrupt factor flags (FFF7H•D1, D0)**

Refer to Section 4.9, "Stopwatch Timer".

#### 4.15.5 Programming notes

- (1) The interrupt factor flags are set when the interrupt condition is established, even if the interrupt mask registers are set to "0".
- (2) After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.
- (3) After an initial reset, all the interrupts including NMI are masked until both the stack pointers SP1 and SP2 are set with the software. Be sure to set the SP1 and SP2 in the initialize routine. Further, when re-setting the stack pointer, the SP1 and SP2 must be set as a pair. When one of them is set, all the interrupts including NMI are masked and interrupts cannot be accepted until the other one is set.

# CHAPTER 5 SUMMARY OF NOTES

## 5.1 Notes for Low Current Consumption

The E0C63567 contains control registers for each of the circuits so that current consumption can be reduced.

These control registers reduce the current consumption through programs that operate the circuits at the minimum levels.

The following lists the circuits that can control operation and their control registers. Refer to these when programming.

*Table 5.1.1 Circuits and control registers*

Circuit (and item)	Control register
CPU	HALT instruction
CPU operating frequency	CLKCHG, OSCC
LCD system voltage circuit	LPWR
SVD circuit	SVDON

Refer to Chapter 7, "Electrical Characteristics" for current consumption.

Below are the circuit statuses at initial reset.

**CPU:** Operating status

**CPU operating frequency:** Low speed side (CLKCHG = "0")

OSC3 oscillation circuit is in OFF status (OSCC = "0")

**LCD system voltage circuit:** OFF status (LPWR = "0")

**SVD circuit:** OFF status (SVDON = "0")

Also, be careful about panel selection because the current consumption can differ by the order of several  $\mu\text{A}$  on account of the LCD panel characteristics.

## 5.2 Summary of Notes by Function

---

Here, the cautionary notes are summed up by function category. Keep these notes well in mind when programming.

### Memory and stack

- (1) Memory is not implemented in unused areas within the memory map. Further, some non-implementation areas and unused (access prohibition) areas exist in the display memory area and the peripheral I/O area. If the program that accesses these areas is generated, its operation cannot be guaranteed. Refer to Section 4.7.4, "Display memory", for the display memory, and the I/O memory maps shown in Tables 4.1.1 (a)–(g) for the peripheral I/O area.
- (2) Part of the RAM area is used as a stack area for subroutine call and register evacuation, so pay attention not to overlap the data area and stack area.
- (3) The E0C63000 core CPU handles the stack using the stack pointer for 4-bit data (SP2) and the stack pointer for 16-bit data (SP1).  
16-bit data are accessed in stack handling by SP1, therefore, this stack area should be allocated to the area where 4-bit/16-bit access is possible (0100H to 01FFH). The stack pointers SP1 and SP2 change cyclically within their respective range: the range of SP1 is 0000H to 03FFH and the range of SP2 is 0000H to 00FFH. Therefore, pay attention to the SP1 value because it may be set to 0200H or more exceeding the 4-bit/16-bit accessible range in the E0C63567 or it may be set to 00FFH or less. Memory accesses except for stack operations by SP1 are 4-bit data access. After initial reset, all the interrupts including NMI are masked until both the stack pointers SP1 and SP2 are set by software. Further, if either SP1 or SP2 is re-set when both are set already, the interrupts including NMI are masked again until the other is re-set. Therefore, the settings of SP1 and SP2 must be done as a pair.

### Watchdog timer

- (1) When the watchdog timer is being used, the software must reset it within 3-second cycles.
- (2) Because the watchdog timer is set in operation state by initial reset, set the watchdog timer to disabled state (not used) before generating an interrupt (NMI) if it is not used.

### Oscillation circuit

- (1) It takes at least 5 msec from the time the OSC3 oscillation circuit goes ON until the oscillation stabilizes. Consequently, when switching the CPU operation clock from OSC1 to OSC3, do this after a minimum of 5 msec have elapsed since the OSC3 oscillation went ON.  
Further, the oscillation stabilization time varies depending on the external oscillator characteristics and conditions of use, so allow ample margin when setting the wait time.
- (2) When switching the clock form OSC3 to OSC1, use a separate instruction for switching the OSC3 oscillation OFF. An error in the CPU operation can result if this processing is performed at the same time by the one instruction.
- (3) The internal operating voltage of VD1 is fixed at 2.1 V. So it is not necessary to control the operating voltage regardless of the operating clock selected.

### Input port

- (1) When input ports are changed from low to high by pull-up resistors, the rise of the waveform is delayed on account of the time constant of the pull-up resistor and input gate capacitance. Hence, when fetching input ports, set an appropriate waiting time. Particular care needs to be taken of the key scan during key matrix configuration. Make this waiting time the amount of time or more calculated by the following expression.  

$$10 \times C \times R$$

C: terminal capacitance 5 pF + parasitic capacitance ? pF  
R: pull-up resistance 330 kΩ
- (2) The K13 terminal functions as the clock input terminal for the programmable timer, and the input signal is shared with the input port and the programmable timer. Therefore, when the K13 terminal is set to the clock input terminal for the programmable timer, take care of the interrupt setting.

### Output port

- (1) When using an output port (R00–R03, R10–R13) for special output, fix the corresponding data register (R00–R03, R10–R13) at "1" and the high impedance control register (R00HIZ–R03HIZ, R10HIZ–R13HIZ) at "0" (data output).  
Be aware that the output terminal is fixed at a low ( $V_{SS}$ ) level the same as the DC output if "0" is written to the data registers when the special output has been selected.  
Be aware that the output terminal shifts into high impedance status when "1" is written to the high impedance control register.
- (2) A hazard may occur when the TOUT, FOUT, BZ or XBZ signal is turned ON and OFF.
- (3) When fOSC3 is selected for the FOUT signal frequency, it is necessary to control the OSC3 oscillation circuit before output.  
Refer to Section 4.3, "Oscillation Circuit", for the control and notes.

### I/O port

- (1) When in the input mode, I/O ports are changed from low to high by pull-up resistor, the rise of the waveform is delayed on account of the time constant of the pull-up resistor and input gate capacitance. Hence, when fetching input ports, set an appropriate wait time.  
Particular care needs to be taken of the key scan during key matrix configuration.  
Make this waiting time the amount of time or more calculated by the following expression.  

$$10 \times C \times R$$
  - C: terminal capacitance 5 pF + parasitic capacitance ? pF
  - R: pull-up resistance 330 k $\Omega$
- (2) When special output (CL, FR) has been selected, a hazard may occur when the signal is turned ON or OFF.

### LCD driver

- (1) When a program that access no memory mounted area (F078H–F0FFH, F178H–F1FFH, F201H, F203H, . . . , F277H) is made, the operation is not guaranteed.
- (2) Because at initial reset, the contents of display memory and LC3–LC0 (LCD contrast) are undefined, there is need to initialize by the software. Furthermore, take care of the registers LPWR and ALOFF because these are set so that the display goes OFF.

### Clock timer

- (1) Be sure to read timer data in the order of low-order data (TM0–TM3) then high-order data (TM4–TM7).
- (2) When the CR oscillation circuit is selected as the OSC1 oscillation circuit by mask option, the frequencies and times differ from the values described in this manual because the oscillation frequency will be 60 kHz (Typ.). Therefore, the clock timer can not be used for the clock function.

### Stopwatch timer

- (1) When data of the counter is read at run mode, perform the reading after suspending the counter once and then set SWRUN to "1" again. Moreover, it is required that the suspension period not exceed 976  $\mu$ sec (1/4 cycle of 256 Hz).
- (2) When the CR oscillation circuit is selected as the OSC1 oscillation circuit by mask option, the frequencies and times differ from the values described in this manual because the oscillation frequency will be 60 kHz (Typ.). Therefore, this timer can not be used for the stopwatch function.

### Programmable timer

- (1) When reading counter data, be sure to read the low-order 4 bits (PTD00–PTD03, PTD10–PTD13) first. Furthermore, the high-order 4 bits (PTD04–PTD07, PTD14–PTD17) should be read within 0.73 msec (when fOSC1 is 32.768 kHz) of reading the low-order 4 bits (PTD00–PTD03, PTD10–PTD13).

- (2) The programmable timer actually enters RUN/STOP status in synchronization with the falling edge of the input clock after writing to the PTRUN0/PTRUN1 register. Consequently, when "0" is written to the PTRUN0/PTRUN1 register, the timer enters STOP status at the point where the counter is decremented (-1). The PTRUN0/PTRUN1 register maintains "1" for reading until the timer actually stops. Figure 5.2.1 shows the timing chart for the RUN/STOP control.

Fig. 5.2.1 Timing chart for RUN/STOP control

It is the same even in the event counter mode. Therefore, be aware that the counter does not enter RUN/STOP status if a clock is not input after setting the RUN/STOP control register (PTRUN0).

- (3) Since the TOUT signal is generated asynchronously from the PTOUT register, a hazard within 1/2 cycle is generated when the signal is turned ON and OFF by setting the register.
- (4) When the OSC3 oscillation clock is selected for the clock source, it is necessary to turn the OSC3 oscillation ON, prior to using the programmable timer. However the OSC3 oscillation circuit requires a time at least 5 msec from turning the circuit ON until the oscillation stabilizes. Therefore, allow an adequate interval from turning the OSC3 oscillation circuit ON to starting the programmable timer. Refer to Section 4.3, "Oscillation Circuit", for the control and notes of the OSC3 oscillation circuit. At initial reset, the OSC3 oscillation circuit is set in the OFF state.

**Serial interface**

- (1) Be sure to initialize the serial interface mode in the transmit/receive disabled status (TXEN = RXEN = "0").
- (2) Do not perform double trigger (writing "1") to TXTRG (RXTRG) when the serial interface is in the transmitting (receiving) operation.
- (3) In the clock synchronous mode, since one clock line ( $\overline{\text{SCLK}}$ ) is shared for both transmitting and receiving, transmitting and receiving cannot be performed simultaneously. (Half duplex only is possible in clock synchronous mode.) Consequently, be sure not to write "1" to RXTRG (TXTRG) when TXTRG (RXTRG) is "1".
- (4) When a parity error or flaming error is generated during receiving in the asynchronous mode, the receiving error interrupt factor flag ISER is set to "1" prior to the receive completion interrupt factor flag ISRC for the time indicated in Table 5.2.1. Consequently, when an error is generated, you should reset the receiving complete interrupt factor flag ISRC to "0" by providing a wait time in error processing routines and similar routines. When an overrun error is generated, the receiving complete interrupt factor flag ISRC is not set to "1" and a receiving complete interrupt is not generated.

Table 5.2.1 Time difference between ISER and ISRC on error generation

Clock source	Time difference
fosc3 / n	1/2 cycles of fosc3 / n
Programmable timer	1 cycle of timer 1 underflow

- (5) When the demultiplied signal of the OSC3 oscillation circuit is made the clock source, it is necessary to turn the OSC3 oscillation ON, prior to using the serial interface. A time interval of 5 msec, from the turning ON of the OSC3 oscillation circuit to until the oscillation stabilizes, is necessary, due to the oscillation element that is used. Consequently, you should allow an adequate waiting time after turning ON of the OSC3 oscillation, before starting transmitting/receiving of serial interface.
- (6) Be aware that the maximum clock frequency for the serial interface is limited to 1 MHz.

## Sound generator

- (1) Since the BZ and XBZ signals are generated asynchronous to the BZE register, hazards may be produced when the signal goes ON/OFF due to the setting of the BZE register.
- (2) The one-shot output is only valid when the normal buzzer output is OFF (BZE = "0") and will be invalid when the normal buzzer output is ON (BZE = "1").
- (3) Since the BZ and XBZ signals are the special outputs of the R01 and R00 ports, it is necessary to set the high impedance control registers (R01HIZ, R00HIZ) to "0", the data registers (R01, R00) to "1" and the output selection registers (BZOUT, XBZOUT) to "1" before setting the BZE register to "1".
- (4) The buzzer signal is generated by dividing the OSC1 oscillation clock. Since the frequencies and times that are described in this manual are the values in the case of crystal oscillation (32.768 kHz, Typ.), they differ when CR oscillation (60 kHz, Typ.) is selected.

## SVD circuit

- (1) To obtain a stable detection result, the SVD circuit must be ON for at least 100  $\mu$ sec. So, to obtain the SVD detection result, follow the programming sequence below.
  1. Set SVDON to "1"
  2. Maintain for 100  $\mu$ sec minimum
  3. Set SVDON to "0"
  4. Read SVDDT
- (2) The SVD circuit should normally be turned OFF because SVD operation increase current consumption.

## Telephone function

- (1) It is necessary to turn the OSC3 oscillation on prior to a dialing operation in tone mode because the tone mode uses the OSC3 (3.58 MHz) clock. However it increases current consumption. Therefore, turn the OSC3 oscillation off after finishing the dialling operation in tone mode.
- (2) Do not write "0" (0000B) to the IDP, FTS, PTS or TCD (in pulse mode) registers because it may cause a malfunction.
- (3) The pause function control bit PAUSE (FF14H•D1) and the flash function control bit FLASH (FF14H•D0) are write-only, so software cannot control these functions (on address FF14H) using an ALU instruction (AND, OR ...). Furthermore, be aware that the pause function or the flash function is canceled when "0" is written to the PAUSE bit (FF14H•D1) or the FLASH bit (FF14H•D0).

## Interrupt

- (1) The interrupt factor flags are set when the interrupt condition is established, even if the interrupt mask registers are set to "0".
- (2) After an interrupt occurs, the same interrupt will occur again if the interrupt enabled state (I flag = "1") is set or the RETI instruction is executed unless the interrupt factor flag is reset. Therefore, be sure to reset (write "1" to) the interrupt factor flag in the interrupt service routine before shifting to the interrupt enabled state.
- (3) After an initial reset, all the interrupts including NMI are masked until both the stack pointers SP1 and SP2 are set with the software. Be sure to set the SP1 and SP2 in the initialize routine. Further, when re-setting the stack pointer, the SP1 and SP2 must be set as a pair. When one of them is set, all the interrupts including NMI are masked and interrupts cannot be accepted until the other one is set.

### 5.3 Precautions on Mounting

#### <Oscillation Circuit>

- Oscillation characteristics change depending on conditions (board pattern, components used, etc.). In particular, when a ceramic oscillator or crystal oscillator is used, use the oscillator manufacturer's recommended values for constants such as capacitance and resistance.
- Disturbances of the oscillation clock due to noise may cause a malfunction. Consider the following points to prevent this:
  - (1) Components which are connected to the OSC1, OSC2, OSC3 and OSC4 terminals, such as oscillators, resistors and capacitors, should be connected in the shortest line.
  - (2) As shown in the right hand figure, make a Vss pattern as large as possible at circumscription of the OSC1, OSC2, OSC3 and OSC4 terminals and the components connected to these terminals. Furthermore, do not use this Vss pattern for any purpose other than the oscillation system.

- In order to prevent unstable operation of the oscillation circuit due to current leak between OSC1/OSC3 and VDD, please keep enough distance between OSC1/OSC3 and VDD or other signals on the board pattern.

#### <Reset Circuit>

- The power-on reset signal which is input to the  $\overline{\text{RESET}}$  terminal changes depending on conditions (power rise time, components used, board pattern, etc.). Decide the time constant of the capacitor and resistor after enough tests have been completed with the application product. When the built-in pull-up resistor is added to the  $\overline{\text{RESET}}$  terminal by mask option, take into consideration dispersion of the resistance for setting the constant.
- In order to prevent any occurrences of unnecessary resetting caused by noise during operating, components such as capacitors and resistors should be connected to the  $\overline{\text{RESET}}$  terminal in the shortest line.

#### <Power Supply Circuit>

- Sudden power supply variation due to noise may cause malfunction. Consider the following points to prevent this:
  - (1) The power supply should be connected to the VDD and VSS terminals with patterns as short and large as possible.
  - (2) When connecting between the VDD and VSS terminals with a bypass capacitor, the terminals should be connected as short as possible.

- (3) Components which are connected to the VD1 and VC1-VC5 terminals, such as capacitors, should be connected in the shortest line. In particular, the VC1-VC5 voltages affect the display quality.
- Do not connect anything to the VC1-VC5 terminals when the LCD driver is not used.

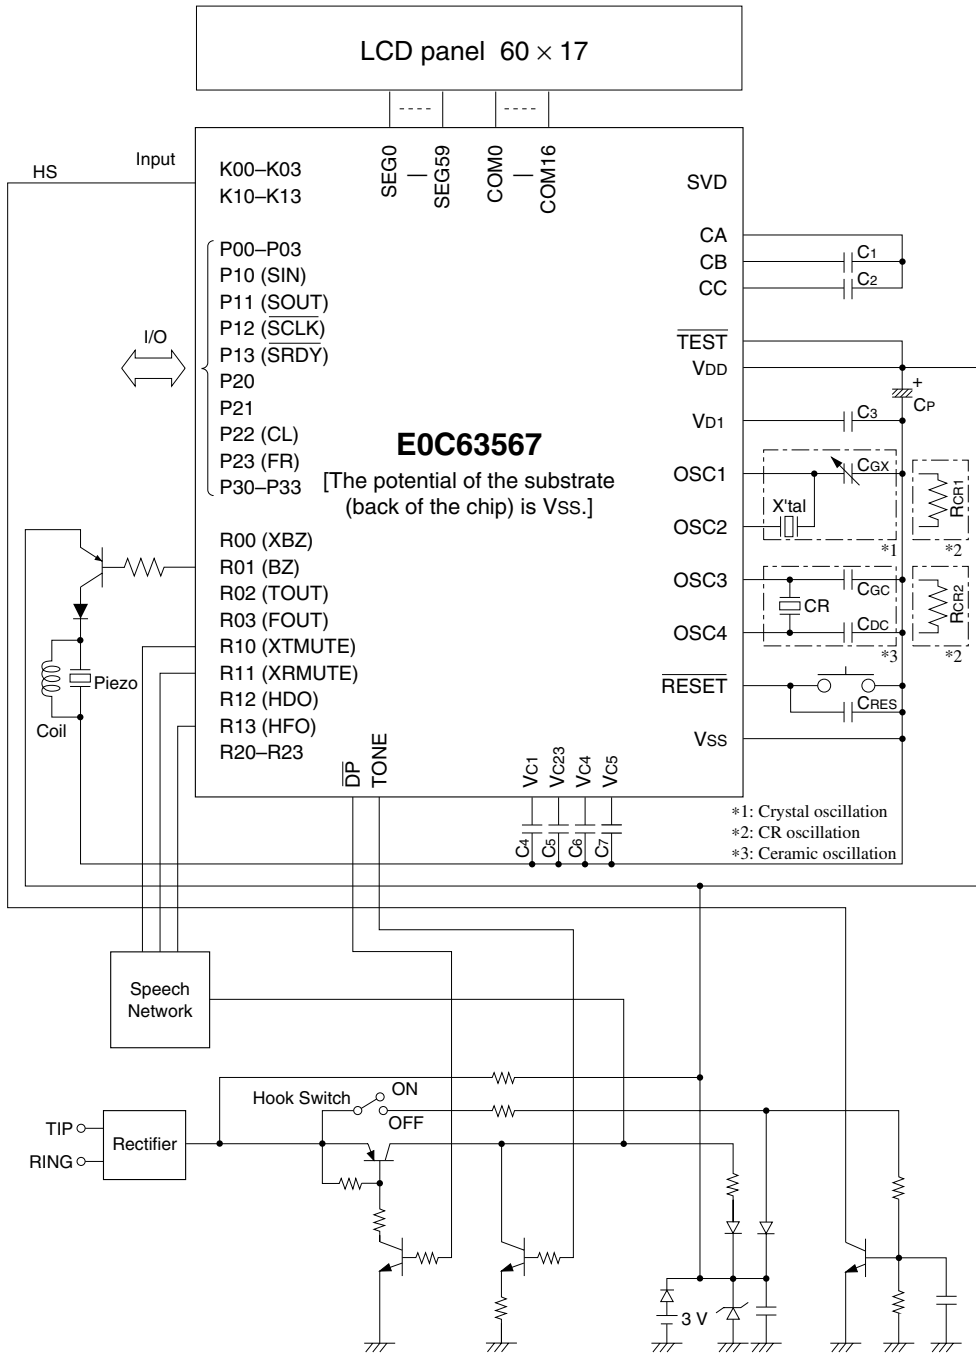

**<Arrangement of Signal Lines>**

- In order to prevent generation of electromagnetic induction noise caused by mutual inductance, do not arrange a large current signal line near the circuits that are sensitive to noise such as the oscillation unit.
- When a signal line is parallel with a high-speed line in long distance or intersects a high-speed line, noise may be generated by mutual interference between the signals and it may cause a malfunction. Do not arrange a high-speed signal line especially near circuits that are sensitive to noise such as the oscillation unit.

**<Precautions for Visible Radiation (when bare chip is mounted)>**

- Visible radiation causes semiconductor devices to change the electrical characteristics. It may cause this IC to malfunction. When developing products which use this IC, consider the following precautions to prevent malfunctions caused by visible radiations.
  - (1) Design the product and implement the IC on the board so that it is shielded from visible radiation in actual use.
  - (2) The inspection process of the product needs an environment that shields the IC from visible radiation.
  - (3) As well as the face of the IC, shield the back and side too.

# CHAPTER 6 BASIC EXTERNAL WIRING DIAGRAM

X'tal	Crystal oscillator	32.768 kHz, C1 (Max.) = 34 kΩ
CGX	Trimmer capacitor	5–25 pF
RCR1	Resistor for OSC1 CR oscillation	600 kΩ (60 kHz)
CR	Ceramic oscillator	3.58 MHz (3.0 V)
CGC	Gate capacitor	30 pF
CDC	Drain capacitor	30 pF
RCR2	Resistor for OSC3 CR oscillation	47 kΩ (1.8 MHz)
C1–C7	Capacitor	0.2 μF
CP	Capacitor	3.3 μF
CRES	RESET terminal capacitor	0.1 μF

*Note: The table is simply an example, and is not guaranteed to work.*

# CHAPTER 7 ELECTRICAL CHARACTERISTICS

## 7.1 Absolute Maximum Rating

(V <sub>SS</sub> =0V)			
Item	Symbol	Rated value	Unit
Supply voltage	V <sub>DD</sub>	-0.5 to 7.0	V
Input voltage (1)	V <sub>I</sub>	-0.5 to V <sub>DD</sub> + 0.3	V
Input voltage (2)	V <sub>IOSC</sub>	-0.5 to V <sub>D1</sub> + 0.3	V
Permissible total output current *1	ΣI <sub>VDD</sub>	10	mA
Operating temperature	T <sub>opr</sub>	-20 to 70	°C
Storage temperature	T <sub>stg</sub>	-65 to 150	°C
Soldering temperature / time	T <sub>sol</sub>	260°C, 10sec (lead section)	–
Permissible dissipation *2	P <sub>D</sub>	250	mW

\*1 The permissible total output current is the sum total of the current (average current) that simultaneously flows from the output pin (or is drawn in).

\*2 In case of plastic package (QFP8-144pin).

## 7.2 Recommended Operating Conditions

(T <sub>a</sub> =-20 to 70°C)						
Item	Symbol	Condition	Min.	Typ.	Max.	Unit
Supply voltage	V <sub>DD</sub>	V <sub>SS</sub> =0V	2.2	3.0	5.5	V
Oscillation frequency	fosc1	Crystal oscillation	–	32.768	–	kHz
		CR oscillation	40	60	80	kHz
	fosc3	CR oscillation	–	1,800	2,250	kHz
		Ceramic oscillation	–	3.58	–	MHz
SVD terminal input voltage	SVD	V <sub>SS</sub> =0V, SVD≤V <sub>DD</sub>	0		5.5	V

### 7.3 DC Characteristics

Unless otherwise specified:

$V_{DD}=3.0V$ ,  $V_{SS}=0V$ ,  $f_{OSC1}=32.768kHz$ ,  $T_a=-20$  to  $70^{\circ}C$ ,  $V_{D1}/V_{C1}/V_{C23}/V_{C4}/V_{C5}$  are internal voltage,  $C_1-C_7=0.2\mu F$

Item	Symbol	Condition	Min.	Typ.	Max.	Unit
High level input voltage (1)	$V_{IH1}$	K00-03, K10-13 P00-03, P10-13, P20-23, P30-33	$0.8 \cdot V_{DD}$		$V_{DD}$	V

\*1 Without panel load. The SVD circuit is OFF.

\*2 OSCC = "0"

\*3 Please input the voltage, which is within the range between V<sub>SS</sub> and V<sub>DD</sub>, into the SVD terminal.

## 7.5 Oscillation Characteristics

The oscillation characteristics change depending on the conditions (components used, board pattern, etc.). Use the following characteristics as reference values.

### OSC1 crystal oscillation circuit

Unless otherwise specified:

$V_{DD}=3.0V$ ,  $V_{SS}=0V$ ,  $f_{OSC1}=32.768kHz$ ,  $C_G=25pF$ ,  $C_D=$ built-in,  $T_a=-20$  to  $70^{\circ}C$

Item	Symbol	Condition	Min.	Typ.	Max.	Unit
Oscillation start voltage	Vsta	$t_{sta} \leq 3sec$ ( $V_{DD}$ )	2.2			V
Oscillation stop voltage	Vstp	$t_{stp} \leq 10sec$ ( $V_{DD}$ )	2.2			V
Built-in capacitance (drain)	CD	Including the parasitic capacitance inside the IC (in chip)		14		pF
Frequency/voltage deviation	$\Delta f/\Delta V$	$V_{DD}=2.2$ to $5.5V$			10	ppm
Frequency/IC deviation	$\Delta f/\Delta IC$		-10		10	ppm
Frequency adjustment range	$\Delta f/\Delta C_G$	$C_G=5$ to $25pF$	10	20		ppm
Harmonic oscillation start voltage	Vhho	$C_G=5pF$ ( $V_{DD}$ )	5.5			V
Permitted leak resistance	Rleak	Between OSC1 and VSS	200			M $\Omega$

### OSC1 CR oscillation circuit

Unless otherwise specified:

$V_{DD}=3.0V$ ,  $V_{SS}=0V$ ,  $R_{CR1}=600k\Omega$ ,  $T_a=-20$  to  $70^{\circ}C$

Item	Symbol	Condition	Min.	Typ.	Max.	Unit
Oscillation frequency dispersion	fosc1		-30	60kHz	30	%
Oscillation start voltage	Vsta	( $V_{DD}$ )	2.2			V
Oscillation start time	tsta	$V_{DD}=2.2$ to $5.5V$			3	mS
Oscillation stop voltage	Vstp	( $V_{DD}$ )	2.2			V

### OSC3 ceramic oscillation circuit

Unless otherwise specified:

$V_{DD}=3.0V$ ,  $V_{SS}=0V$ , Ceramic oscillator:  $3.58MHz$ ,  $C_G=C_D=30pF$ ,  $T_a=-20$  to  $70^{\circ}C$

Item	Symbol	Condition	Min.	Typ.	Max.	Unit
Oscillation start voltage	Vsta	( $V_{DD}$ )	2.2			V
Oscillation start time	tsta	$V_{DD}=2.2$ to $5.5V$			5	mS
Oscillation stop voltage	Vstp	( $V_{DD}$ )	2.2			V

### OSC3 CR oscillation circuit

Unless otherwise specified:

$V_{DD}=3.0V$ ,  $V_{SS}=0V$ ,  $R_{CR2}=47k\Omega$ ,  $T_a=-20$  to  $70^{\circ}C$

Item	Symbol	Condition	Min.	Typ.	Max.	Unit
Oscillation frequency dispersion	fosc3		-25	1,800kHz	25	%
Oscillation start voltage	Vsta	( $V_{DD}$ )	2.2			V
Oscillation start time	tsta	$V_{DD}=2.2$ to $5.5V$			3	mS
Oscillation stop voltage	Vstp	( $V_{DD}$ )	2.2			V

**OSC1 CR oscillation frequency-resistance characteristic**

The oscillation characteristics change depending on the conditions (components used, board pattern, etc.). Use the following characteristics as reference values and evaluate the characteristics on the actual product.

**OSC3 CR oscillation frequency-resistance characteristic**

The oscillation characteristics change depending on the conditions (components used, board pattern, etc.). Use the following characteristics as reference values and evaluate the characteristics on the actual product.

## 7.6 Serial Interface AC Characteristics

### Clock synchronous master mode

•During 32 kHz operation

Condition:  $V_{DD}=3.0V$ ,  $V_{SS}=0V$ ,  $T_a=-20$  to  $70^{\circ}C$ ,  $V_{IH1}=0.8V_{DD}$ ,  $V_{IL1}=0.2V_{DD}$ ,  $V_{OH}=0.8V_{DD}$ ,  $V_{OL}=0.2V_{DD}$

Item	Symbol	Min.	Typ.	Max.	Unit
Transmitting data output delay time	t <sub>smd</sub>			5	μS
Receiving data input set-up time	t <sub>sms</sub>	10			μS
Receiving data input hold time	t <sub>smh</sub>	5			μS

•During 1 MHz operation

Condition:  $V_{DD}=3.0V$ ,  $V_{SS}=0V$ ,  $T_a=-20$  to  $70^{\circ}C$ ,  $V_{IH1}=0.8V_{DD}$ ,  $V_{IL1}=0.2V_{DD}$ ,  $V_{OH}=0.8V_{DD}$ ,  $V_{OL}=0.2V_{DD}$

Item	Symbol	Min.	Typ.	Max.	Unit
Transmitting data output delay time	t <sub>smd</sub>			200	nS
Receiving data input set-up time	t <sub>sms</sub>	400			nS
Receiving data input hold time	t <sub>smh</sub>	200			nS

Note that the maximum clock frequency is limited to 1 MHz.

### Clock synchronous slave mode

•During 32 kHz operation

Condition:  $V_{DD}=3.0V$ ,  $V_{SS}=0V$ ,  $T_a=-20$  to  $70^{\circ}C$ ,  $V_{IH1}=0.8V_{DD}$ ,  $V_{IL1}=0.2V_{DD}$ ,  $V_{OH}=0.8V_{DD}$ ,  $V_{OL}=0.2V_{DD}$

Item	Symbol	Min.	Typ.	Max.	Unit
Transmitting data output delay time	t <sub>ssd</sub>			10	μS
Receiving data input set-up time	t <sub>sss</sub>	10			μS
Receiving data input hold time	t <sub>ssh</sub>	5			μS

•During 1 MHz operation

Condition:  $V_{DD}=3.0V$ ,  $V_{SS}=0V$ ,  $T_a=-20$  to  $70^{\circ}C$ ,  $V_{IH1}=0.8V_{DD}$ ,  $V_{IL1}=0.2V_{DD}$ ,  $V_{OH}=0.8V_{DD}$ ,  $V_{OL}=0.2V_{DD}$

Item	Symbol	Min.	Typ.	Max.	Unit
Transmitting data output delay time	t <sub>ssd</sub>			500	nS
Receiving data input set-up time	t <sub>sss</sub>	400			nS
Receiving data input hold time	t <sub>ssh</sub>	200			nS

Note that the maximum clock frequency is limited to 1 MHz.

<Master mode>

<Slave mode>

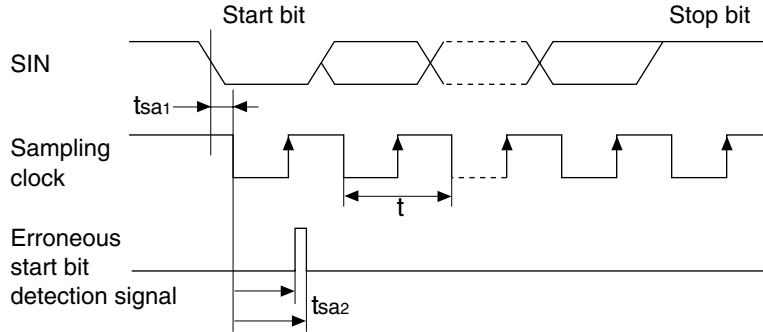

### Asynchronous system

Condition:  $V_{DD}=2.2$  to  $5.5V$ ,  $V_{SS}=0V$ ,  $T_a=-20$  to  $70^{\circ}C$

Item	Symbol	Min.	Typ.	Max.	Unit
Start bit detection error time *1	$t_{sa1}$	0		$t/16$	S
Erroneous start bit detection range time *2	$t_{sa2}$	$9t/16$		$10t/16$	S

\*1 Start bit detection error time is a logical delay time from inputting the start bit until internal sampling begins operating. (Time as far as AC is excluded.)

\*2 Erroneous start bit detection range time is a logical range to detect whether a LOW level (start bit) has been input again after a start bit has been detected and the internal sampling clock has started. When a HIGH level is detected, the start bit detection circuit is reset and goes into a wait status until the next start bit. (Time as far as AC is excluded.)

## 7.7 Timing Chart

### System clock switching

## 7.8 Characteristic Curves (reference value)

### 7.8.1 Output current characteristics

#### High level output current (Pxx, Rxx, BZ)

#### Low level output current (Pxx, Rxx, BZ)

**High level output current (SEGxx)**

**Low level output current (SEGxx)**

7.8.2 Power current - frequency characteristics

Ceramic oscillation (during operation)

# CHAPTER 8 PACKAGE

## 8.1 Plastic Package

QFP8-144pin

(Unit: mm)

The dimensions are subject to change without notice.

## 8.2 Ceramic Package for Test Samples

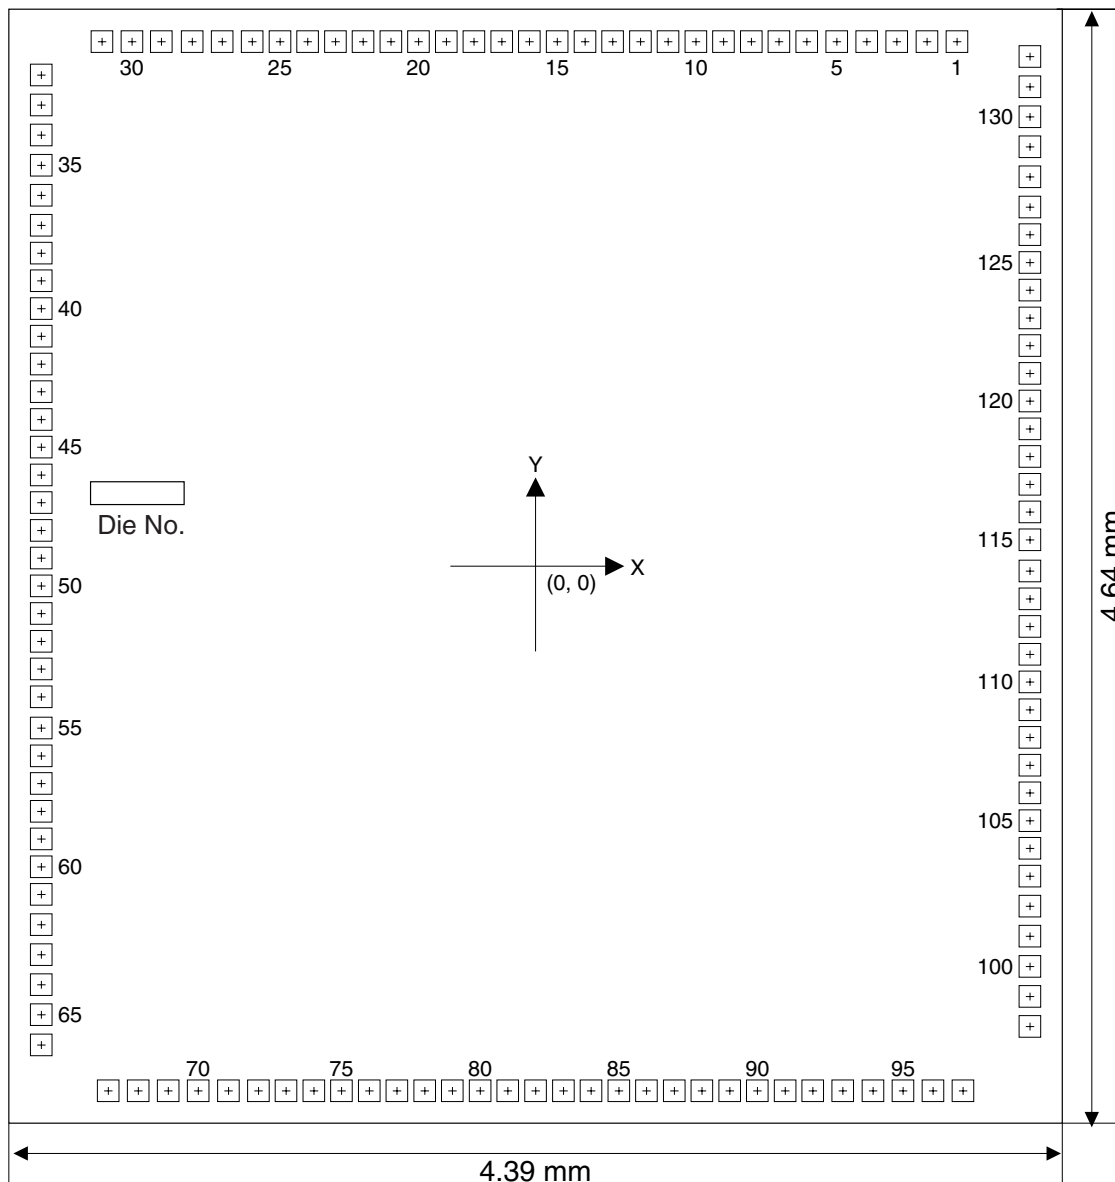

### QFP8-144pin

(Unit: mm)

# CHAPTER 9 PAD LAYOUT

## 9.1 Diagram of Pad Layout

Chip thickness: 400  $\mu$ m  
 Pad opening: 100  $\mu$ m

## 9.2 Pad Coordinates

Unit:  $\mu\text{m}$
